# Colorimetric detection of HVA by self-assembly of Au nanorods with DNA double helices to give side-by-side and end-to-end structures†

Lin Chang,‡ Younas Khan,‡ Lidong Li,\* Nan Yang, Penggang Yin and Lin Guo

In this article we present the self-assembly of gold nanorods with DNA double helices into side-by-side and end-to-end structures by the addition of HVA (hepatitis A virus Vall7 polyprotein gene). Between every two gold nanorods, there is a distance of 10.2 nm which agrees with the length of DNA. By observing the change in color with the naked eye or UV-Vis spectral absorbance, HVA concentration can be quantitatively measured. The colorimetric detection has a linear relationship between the UV-Vis spectral absorbance and the concentration, with a detectable range of 0.05 pM to 35 pM. The standard deviation " $R^2$ " value was found to be >0.99. This method is simple, time economic and highly sensitive, and a lower limit of detection up to 0.05 pM HVA can be achieved with great selectivity.

## 1. Introduction

Self-assembly promotes many good properties in nanoparticles such as unique optical, magnetic and electric properties and so on, which leads many scientists to pay close attention to self-assembly in nanoscale particles.<sup>1–5</sup> Gold nanorods (Au NRs) have attracted wide interest due to their good optical properties, which result from the localized surface plasmon resonance, relative to the local dielectric environment.<sup>6–9</sup> Self-assembled Au NRs have many potential applications in biology and science.<sup>10</sup> A number of methods, for example using nano-templates,<sup>11</sup> crystallization,<sup>12</sup> bio-molecules,<sup>13</sup> and small molecules<sup>14</sup> have been reported to transform dispersed nanoparticles into desirable assembled structures. Many substances such as DNA,<sup>15</sup> organic molecules,<sup>17–19</sup> polymers,<sup>20</sup> biotin-streptavidin connectors,<sup>21</sup> and those in the antibody-antigen reaction<sup>16</sup> can bring Au NRs together into ideal patterns through base pairing or physical and chemical affinities. Among these, DNA is a similar size to nanoscale particles and has a strong affinity for forming inter-connected structures<sup>22</sup> based on oligonucleotide-gold nanorod conjugates (DNA-Au NR) by base sequence matching.

Due to their size and distance dependent optical properties and chemical stability, oligonucleotide-gold nanoparticle conjugates are found to be promising colorimetric probes. Until now, DNA-AuNP conjugates have been widely applied in the detection field, monitoring certain specific metal ions, organic

molecules and some large molecules.<sup>23–27</sup> Nam J. M.<sup>28</sup> has used DNA-AuNPs to detect cancer biomarker proteins (PSA) with good sensitivity up to 3 attomolar. Jae-Seung Lee<sup>29</sup> has applied DNA-functionalized gold nanoparticles to the detection of Hg<sup>2+</sup>. Moreover, Min Su Han<sup>30</sup> reported a simple detection method for an organic molecule using DNA-functionalized gold nanoparticles.

Hepatitis A is an acute infectious disease of the liver caused by the hepatitis A virus (HAV).<sup>31</sup> Many cases have little to no symptoms especially in the young. The time between infection and symptoms is two to six weeks. When symptoms occur, they usually last eight weeks, with a fever, jaundice, diarrhea and abdominal pain. It usually spreads through close contact such as by drinking contaminated water or eating contaminated food with an infectious person.<sup>32</sup> The hepatitis A virus Vall7 polyprotein gene (HVA) is the kind of polyprotein that exists in HAV, and can be used as a biomarker for HAV to identify infected people so that we can prevent the virus spreading. A number of methods have been used for the detection of HVA such as magnetic fluorescence<sup>33</sup> with a detection limit up to 0.1 pM, Raman spectroscopy<sup>34</sup> with a detection limit up to 1 pM, antibodies based on enzyme immunoassays (EIAs) and radioimmuno assays (RIAs)<sup>35</sup> with detection limits up to 1 pM and an SPR based colorimetric method with a detection limit up to 10 pM.<sup>36</sup> But all these methods are quite complicated while some have limitations regarding sensitivity for detecting very small concentrations of HVA, so we need to develop an easy, sensitive and highly reliable method for early HVA detection.

In this work, we demonstrate the synthesis of Au NRs and the controllable self-assembly of Au NRs into novel structures including side-by-side and end-to-end structures through base pairing with DNA. Based on programmed assembly, we developed a colorimetric method observing a change in solution

color from purple to light pink and used it in the early detection of the hepatitis A virus Vall7 polyprotein gene (HVA). Our method has some obvious advantages over the prevalent methods, firstly it is simple, easy and less time consuming. Secondly, it was found to be very sensitive for HVA. Finally, it is the first time that we have combined self-assembly and colorimetry to detect HAV and with a good result.

## 2. Experimental section

### 2.1 Chemicals

All the DNA and real blood serum samples were bought from Sangon Biotech (Shanghai) Co., Ltd. The sequences are listed in Table 1.  $\text{HAuCl}_4 \cdot 4\text{H}_2\text{O}$  was bought from Shenyang Jinke reagent company. Hexadecyltrimethylammonium bromide (CTAB), hexadecyltrimethylammonium chloride (CTAC), sodium oleate (NaOL), silver nitrate ( $\text{AgNO}_3$ ), sodium borohydride ( $\text{NaBH}_4$ ), hydrochloric acid (HCl, 12.1 M), ascorbic acid (AA), tris(2-carboxylethyl) phosphorus hydrochloride (TCEP), tris(hydroxyethyl)methyl amino methane ( $\text{C}_4\text{H}_{11}\text{NO}_3$ ), magnesium chloride ( $\text{MgCl}_2$ ), and sodium dodecyl sulfate (SDS) were brought from Beijing Chemical Works. All the reagents were analytical grade.

### 2.2 Instruments

Scanning electron microscope (SEM) images were obtained using a Hitachi S-4800. SEM samples were prepared by dropping the test solution onto a silicon chip and leaving it at room temperature until the solvent evaporated. Transmission electron microscopic (TEM) information was obtained using a JEM-2010F operating under a 200 kV acceleration voltage. By dropping the sample solution onto a copper grid with 300 mesh, the test samples were prepared. UV-Vis spectra were obtained using an Alpha-1860C. The samples were prepared by dropping the solution into Ultra-Micro Cells with a thickness of 1 cm and the data was processed and acquired using Origin Lab software.

### 2.3 Preparation of Au NRs

The seed solution was synthesized as follows. Typically, 5 mL of 0.5 mM  $\text{HAuCl}_4$  and 5 mL of 0.2 M CTAB solutions were mixed in a 20 mL transparent vial. Then 1 mL of 0.006 M fresh  $\text{NaBH}_4$  solution was added into the vial abovementioned under stirring at a speed of 1200 rpm for 2 min. The color of the solution transformed from yellow to brownish yellow.

Then the vials were placed at room temperature for aging for up to 30 min. Next, we prepared the growth solution as follows: 1.234 g of NaOL and 6.15 g of CTAC were dissolved in 250 mL of water at 50 °C, and were then transferred into a flask. When the temperature had cooled down to 30 °C, 18 mL of 4 mM  $\text{AgNO}_3$  solution and 250 mL of 1 mM  $\text{HAuCl}_4$  solution were added. Then the mixture was left at 30 °C for 15 min, followed by stirring at 7000 rpm for 150 min. Subsequently, 5.0 mL of 12.1 M HCl was employed to adjust the solution to the proper pH which was followed by slow stirring at 400 rpm. Before strong stirring for 30 s, 1.25 mL of 0.064 M AA was introduced. Finally, 0.8 mL of seed solution was dropped into the growth solution and afterwards the mixture was stirred for 30 s, then it was kept still which was helpful for the NR's growth. The produced Au NRs were purified by centrifugation of the products for 25 min at 6000 rpm which was repeated 3 times.<sup>37</sup>

### 2.4 Pretreatment of DNA

Before using DNA as an interconnector, we added a certain amount of TCEP into the DNA solution (DNA was dissolved in 0.001 M Tris-HCl buffer which included 20 mM  $\text{MgCl}_2$  and 0.01% SDS), then the DNA was heated to 90 °C for 5 min to make it more flexible for the following base pairing. TCEP could reduce the disulfide bonds into individual -SH groups which were intended to react on the gold surface.<sup>38</sup>

### 2.5 Self-assembly of Au NRs

Freshly synthesized Au NRs were observed under the SEM (Fig. 1a) and have a length of  $90 \pm 5$  nm and a width of  $25 \pm 5$  nm and were well dispersed. To obtain side-by-side structures, two vials were needed. Helper DNA was added into two vials of Au NRs and incubated for 12 h at room temperature. Before incubating for another 12 h, capture DNA 1 and capture DNA 2 in the same quantities were injected into each vial respectively. Then the two vials were mixed together in a big vial and target DNA was introduced into the big vial. The vial was then heated to 95 °C for 5 min and then the vial was allowed to cool down to room temperature. The helper DNA does not match any other DNA during the process of self-assembly. It is just a kind of DNA to be used as a barrier to control the regioselectivity of the self-assembly, so that we can obtain side-by-side structures. Capture DNA 1 and capture DNA 2 are employed in both the side-by-side structure and end-to-end structure to match with part of the complementary target DNA simultaneously at the ends. The target DNA is like a person with two hands, on the left it joins one of its hands with capture DNA 1 while on the right it joins the other hand with capture DNA 2. To obtain end-to-end structures, the process was similar to the process for side-by-side assembly but in the absence of the helper DNA. Capture DNA 1 and capture DNA 2 were injected into two separate vials and incubated for 12 h. Then the two vials were mixed together in a big vial and target DNA was introduced into the big vial. The vial was then heated to 95 °C for 5 min and then the vial was allowed to cool down to room temperature.

**Table 1** DNA names and sequences used in the experiment (control DNA 1 and 2 were used for the selectivity test)

DNA name	Sequence (5' → 3')
Helper	AAA AAA AAA AAA $\text{C}_{(6)}$ -SH
Target DNA	TTAGAGTTGCATGGATTAACCTCTTCT
Capture DNA 2	HS- $\text{C}_{(6)}$ AGAAAGAGGA
Control DNA 1	TAAAAGTTGCAGGGATTAACCCCCCTTCT
Control DNA 2	TTTGATTGCAGGGTTAAATCCTCTTCT

Fig. 1 (a) SEM images of dispersed Au NRs, the scale bars are 200 nm, 100 nm and 20 nm; (b) TEM images of Au NRs assembled into side-by-side structures (the concentration of  $C_1$  and  $C_2$  was 33 pM, helper was 10 pM, and T was 0.05 pM; 0.5 pM; 1.25 pM; 5 pM; 10 pM; and 35 pM), the scale bar is 50 nm.

### 3. Results and discussion

#### 3.1 Preparation of NR assemblies into regiospecific geometries

Regular NRs (length: 90 nm; width: 25 nm) were synthesized by a classical seed-mediated growth method. Then their surfaces

were modified by single-stranded DNA (ssDNA) at the ends (see Schemes 1 and 2).

During the process of the synthesis, there was still cetyltrimethylammonium bromide (CTAB) which remained coated on the surface of the Au NRs. CTAB preferred to bind to the {100} facet which was the longitudinal side of the Au NRs, and left the {110} facet ends of the Au NRs with a thinner

Scheme 1 Schematic of side-by-side self-assembly.

Scheme 2 Schematic of end-to-end self-assembly.

Fig. 2 UV-Vis spectrum of side-by-side assembly with a target DNA concentration range of 0.05–35 pM (the concentration of  $C_1$  and  $C_2$  was 33 pM, and helper was 10 pM).

Fig. 3 Linear relationship between the absorbance with the change in concentration of target DNA ( $C_1$  and  $C_2$  were 33 pM, and helper was 10 pM for side-by-side structures), T was 0.12 pM; 0.25 pM; 0.5 pM; 2.5 pM; 5.0 pM; 10 pM; and 20 pM. The error bars indicate the standard deviation of the seven successive measurements of a sample for each assay.

coating<sup>39,40</sup> than on their sides. So when in a low concentration of thiolated DNA, it will only attach at the ends and control the geometry.

In this work, two self-assembly methods of Au NRs are presented, side-by-side and end-to-end. These two distinct structures were obtained using different thiolated DNA samples with some specific sequences in an appropriate concentration. As such, we denoted a 10 base thiolated DNA sample with a sequence of GCAACTCTAA  $C_{(6)}$ -SH as capture DNA 1 ( $C_1$ : red in Scheme 1) and another 10 base thiolated DNA sample with a sequence of HS- $C_{(6)}$  AGAAAGAGGA as capture DNA 2 ( $C_2$ : blue in Scheme 1). These two DNA samples had the same function, base pairing with a 30 base target DNA sample (T: green in Scheme 1) at each of the ends which had a sequence of TTA, GAG, TTG, CAT, GGA, TTA, ACT, CCT, CTT, or TCT. An assistant thiolated DNA sample was also employed named helper DNA (H: purple in Scheme 1) with a 15 base simple sequence of AAA AAA AAA  $C_{(6)}$ -SH. The helper DNA is helpful to control the regioselectivity in the self-assembly process, especially during the side-by-side process, but does not match with any other oligomers.

### 3.2 Side-by-side self-assembly

Because the ends have less CTAB on their surface and the ends of Au NRs are more active than the sides of Au NRs,<sup>41</sup> when the helper DNA at an appropriate concentration was added it had a preference to be absorbed at the ends (Scheme 1), which meant that the Au NRs' ends were occupied and that the sides were relatively more active. Then the Au NRs were modified with  $C_1$  (capture DNA 1) or  $C_2$  (capture DNA 2) on their sides, and once a concentration of target DNA between 0.05 pM and 40 pM was injected, there was an effective side-by-side self-assembly (TEM; Fig. 1b) which increased with the increase in target DNA concentration. After self-assembly, the optical properties were similar to nanowires (NWs), which was demonstrated using UV-Vis spectroscopy (Fig. 2).<sup>42,43</sup> With the increase in concentration of the target DNA in the range of 0.05–40 pM, the “nanowires” became fat, which was confirmed by a peak shift. The transverse peaks were inclining to blue shift (shorter wavelength) from 525 nm to 521 nm and decrease in amplitude while the longitudinal surface plasmon peaks red shifted

Fig. 4 TEM images of Au NRs assembled into end-to-end structures (the concentration of  $C_1$  and  $C_2$  was 33 pM), the scale bar is 50 nm.

Fig. 5 UV-Vis spectra of end-to-end assembly with a target DNA concentration range of 0.05–40 pM (the concentration of  $C_1$  and  $C_2$  was 33 pM).

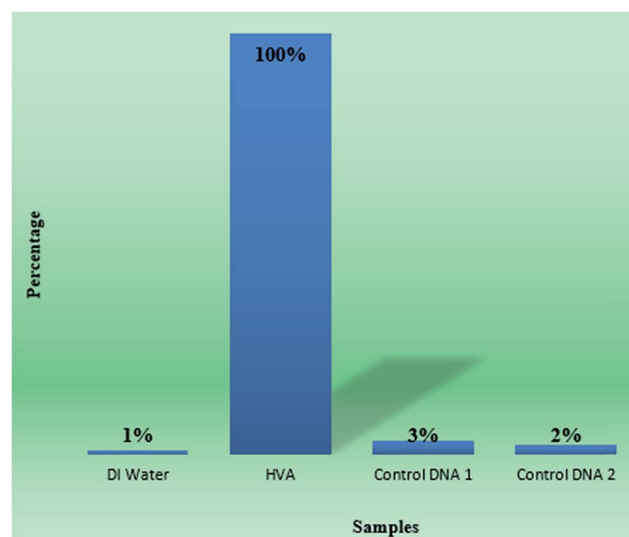

Fig. 6 The bar graph between second deionized water, 1 microlitre HVA, 1 microlitre control DNA 1 and 1 microlitre control DNA 2 shows the selectivity of the method, quantitatively.

(longer wavelength) from 742 nm to 751 nm and decreased in amplitude compared to the Au NRs' peaks. When the concentration of target DNA was lower than 0.05 pM, side-by-side self-assembly was not observed. When the concentration of target DNA was higher than 35 pM, the Au NRs aggregated. Under these two situations, we did not see the behavior of self-assembly, so in our work a target DNA concentration of 0.05–35 pM was found to be optimum under our experimental conditions.

**3.2.1 Colorimetric detection.** During the process of side-by-side self-assembly we found that the solution changed color from light pink to pink and finally became purple with increasing target concentration (Fig. S2†). This gave us a quantitative estimation of HVA concentration by observing the color with the naked eye. As shown in Scheme 1, because helper DNA was firstly added to preoccupy and passivate the ends of the Au nanorods, this left the sides of the Au nanorods open to hybridize with the capture DNA. Afterwards, the target DNA (HVA) was added to hybridize with the capture DNA 1 on the one

side and hybridize with capture DNA 2 on the other side, then linking up all the capture DNA modified gold nanorods by attaching to each other side by side. Then aggregation occurs with an increased concentration of HVA. A linear relation between the target DNA concentration and absorbance was found during UV Visible spectroscopic studies of the various concentrations ranging from 0.5 pM to 40 pM, as shown in Fig. 3. The linear correlation range was found between 0.5 pM and 40 pM with an  $R^2$  value  $>0.99$ . This is the first time that a method has had a low detection limit of 0.05 pM for target DNA (HVA) which is a part of the hepatitis A virus.

### 3.3 End-to-end self-assembly

Compared with the side-by-side structures, the procedure is easier to get end-to-end assembly structures. As show in Scheme 2, end-to-end assembly can be obtained without the addition of helper DNA. Because the ends of the Au nanorod are more active than the sides, adding an appropriate amount of  $C_1$  and  $C_2$  DNA

Fig. 7 UV-Vis spectra of the tests on real samples with side-to-side structures. In the samples, we added Au NRs, a real blood serum sample and HVA with concentrations of 2.5 pM, 10 pM, 20 pM, and 30 pM.

Table 2 Recovery of HVA under different target DNA concentrations

(Target) $C_0$ /pM	A	(Target) $C$ /pM	Recovery (%)
0.125	0.6998	0.1125	90
0.25	0.7366	0.23	92
0.5	0.7812	0.475	95
1.25	0.8452	1.1625	93
2.5	0.8801	2.30	94
10	0.9485	9.4	94
20	0.9934	18.6	93
30	1.025	28.2	94

will firstly attach to the ends of the Au nanorod, and later addition of HVA will result in end-to-end assembly structures (TEM; Fig. 4). Similarly, with the concentration increase of target DNA, the nanowires became longer which was confirmed by peak shifting in the UV-Vis spectra compared to Au NRs' peaks. The transverse peaks remained unchanged in amplitude and wavelength while the longitudinal surface plasmon peaks red shifted (longer wavelength) from 745 nm to 749 nm and decreased in amplitude compared with Au NRs', as shown in Fig. 5. However, there is not a good calibration curve for the end-to-end structures (Fig. S1†).

### 3.4 The selectivity of the colorimetric method

Another vital factor for a colorimetric method is its selectivity which was tested here using a control experiment. Simultaneously, equal concentrations of 1.0  $\mu$ L double deionized water, 1.0  $\mu$ L HVA, 1.0  $\mu$ L control DNA 1 and 1.0  $\mu$ L control DNA 2 were added into two solutions, one containing capture DNA 1 at 33 pM and one containing capture DNA 2 at 33 pM, which were both incubated at room temperature for 12 h and then mixed together. Observed from the colors of the solutions, only the vial

where we added the target DNA had faded a little while the colors of the competitors stayed the same color as with the Au NRs. The results show that this method has good selectivity as shown in Fig. S3† and 6.

### 3.5 Real sample analysis

Many interruptions may occur when a real blood serum sample is employed in this analysis owing to the complexity of a real blood serum sample which can introduce some unknown bonding to the bulk sample. So we needed do some investigations to ensure whether the method was applicable to a real blood serum sample. Firstly, we diluted the blood serum fifty-times, aiming to decrease the background noise in the real sample analysis application. Then under different concentrations of HVA with diluted serum, artificial physiological matrix and spiked serum samples were tested. The experimental data suggests that the method is applicable since the absorbance of the real blood serum samples was only decreased by 0.02 compared to the HVA in double deionized water sample, which was used as the background. So the dilution of a real blood serum sample to a large extent is good to diminish the background noise.

Then we applied the method to the real blood serum sample (Fig. 7) to test whether HVA gave similar results as in the previous experiment, and simultaneously we calculated the recovery of HVA as shown in Table 2. Recovery of HVA was calculated as the ratio between the concentration of added HVA and the detected concentration of HVA. In the table, we obtained very good recoveries between 90% and 94%, which suggests the method has a promising future for use in biological samples.

## 4. Conclusions

Self-assembled oligonucleotide gold nanoparticle conjugates (DNA-AuNP) are found to be promising probes in bio-detection. We described the self-assembly of Au NRs synthesized by a seed-mediated growth method into novel structures: side-by-side and end-to-end. An assay based on the side-by-side structures was developed to detect HVA, a polyprotein in hepatitis A virus. We found our method to be very sensitive with a lower limit of detection up to 0.05 pM. We achieved a linear relationship between the absorbance and the concentration in the range of 0.05 pM to 35 pM with a standard deviation " $R^2$ " value  $>0.99$ . The novel side-by-side structure was attractive because it was convenient and rapid to synthesize and could be promising in detecting a variety of bio-molecules.
