New quinacridone derivatives with π -extended conjugation in central core†

Piotr Kurzep,^a Łukasz Skórka,^a Malgorzata Zagorska,^a Piotr A. Guńka,^a
Marzena Banasiewicz,^b Bolestaw Kozankiewicz^b and Irena Kulszewicz-Bajer^{*a}

A novel synthetic strategy for the preparation of quinacridone derivatives with extended conjugation in central aromatic core is proposed allowing for fine tuning of their electronic properties. Two new quinacridone derivatives with carbazole (1) and naphthalene (2) core are described, which are excellent candidates for optoelectronic applications as evidenced by their electrochemically determined redox properties combined with strong photoluminescence (the fluorescence quantum yield of 0.83 and the radiative rate constant of $90.2 \times 10^7 \text{ s}^{-1}$ in the case of 2).

Introduction

Quinacridone, **QA**, is a well-known industrial dye. Due to its excellent thermal and environmental stabilities it is commonly used for fabrication of paints and inkjet toners. However, recently **QA** has also attracted considerable attention as an organic semiconductor exhibiting interesting luminescent,¹ transport^{1d,2} and photovoltaic³ properties. **QA** and its derivatives have been successfully used as efficient electron transporting layers⁴ or organic emitters in OLEDs with low driving voltage and high power efficiency.^{1b,1e} Copolymers of **QA** and fluorene yield white electroluminescence.⁵ The planar structure of **QA** and its strong H-bonding properties favor its charge transport abilities. As a consequence **QA** and its polymeric derivatives exhibit high charge carrier mobility in organic field-effect transistors.²

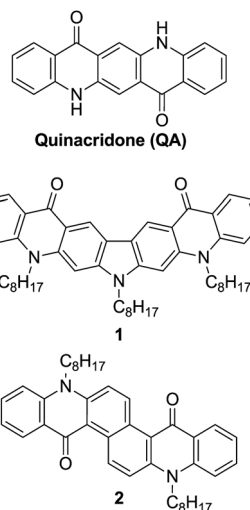

physicochemical properties of this semiconductor can be obtained by the elongation of its π -conjugated structure. Till now the π -conjugation has been extended by the addition of aromatic moieties to lateral phenylene rings of pristine **QA**. Thus, quinacridone derivatives containing indole,^{1d} indene⁸ and dithianaphthene^{2d} rings fused to **QA** have been synthesized. On the other hand, the electronic structure can be also changed by the modification of the central aromatic core of quinacridone. However, the classical method of **QA** preparation is not compatible with this type of modification.^{1a,9} Here, we present a new strategy for tuning the properties of **QA**-type derivatives by the incorporation of different aromatic cores into the center of the **QA** molecule (Scheme 1).

The synthesis of the new compounds (1 and 2) is based on the C–N coupling reaction. It was shown earlier that the

Results and discussion

Synthetic strategy

Physicochemical properties of **QA** can be easily tuned by modification of its chemical structure. Thus, the incorporation of new functional groups on amine^{1a,6} or carbonyl sites⁷ changes the solubility, planarity and the electronic structures of these derivatives. However, the most significant modification of the

Scheme 2 Synthetic pathways leading to **1** and **2**.

Ullmann condensation of anthranilic acid with dihalogenobenzene in the presence of the Cu catalyst requires the use of diiodo-derivatives and leads to a mixture of mono- and disubstituted products, obtained with low to medium yields.¹⁰ Dibromoderivatives are even less reactive in this reaction.¹⁰ However, the coupling in the presence of the palladium catalyst is significantly more efficient, but it largely depends on the reaction conditions. Thus, the amination reactions of 1,3-dibromobenzene with anthranilic acid in the presence of $\text{Pd}(\text{OAc})_2/\text{BINAP}^{10b}$ or 1,2-dibromobenzene with methyl anthranilate using $\text{Pd}(\text{OAc})_2/t\text{-Bu}_3\text{P}$ catalytic system proceeds in sufficiently good yields of 70–80%.¹¹

Taking into consideration these results we have applied the palladium catalyzed C–N coupling for the amination of *para*-substituted dibromoarenes (Scheme 2). The reactions of methyl anthranilate with 2,7-dibromocarbazole using catalytic system $\text{Pddba}_2/t\text{-Bu}_3\text{P}$ or with 2,6-dibromonaphthalene in the presence of $\text{Pd}(\text{OAc})_2/t\text{-Bu}_3\text{P}$ led to the intermediate products **3a** and **4a** with 53% and 90% yields, respectively. Diesters **3a** and **4a** were easily hydrolyzed in NaOH/EtOH solution to the corresponding diacids **3b** and **4b**. Then, diacids were condensed in standard conditions using polyphosphoric acid/ P_2O_5 mixture. Since these condensation products were sparingly soluble they were directly alkylated with *n*-octyl bromide. The final yields were 30% and 56% for carbazole and naphthalene derivatives, respectively. In the case of the derivative **2** the cyclization reaction proceeded only at α positions of naphthalene. No other isomers corresponding to ring-closure at β position were detected. It should be emphasized that this simple route is a rather general method, and should allow to synthesize a new class of

quinacridone derivatives, in which π -conjugation is extended by the incorporation of different aromatic cores in the center of the **QA** molecule.

Electrochemical studies

The electrochemical properties of the compounds **1** and **2** were studied by cyclic voltammetry (CV) (see ESI†) and differential pulse voltammetry (DPV) and compared to that of *N,N'*-dioctylquinacridone, **QA-C8**. The electrochemical behavior of the studied compounds in the positive potential range strongly depended on the nature of the central aromatic core. Thus, the differential pulse voltammogram of **1** exhibited three reversible redox couples at 0.55 V, 0.66 V and 0.99 V (vs. Fc/Fc^+) (Fig. 1a). The first two peaks overlapped and were typical of the carbazole moiety oxidation.^{12a} The third peak was ascribed to the oxidation of acridone unit and its potential was shifted to higher value than that measured for **QA-C8**, due to the positive charge imposed on the molecule in the process of the carbazole core oxidation. Similar oxidation behavior was observed by Wang *et al.* for **QA** substituted at 2,9 positions with carbazole dendrimers.^{1c}

The differential pulse voltammogram of **2**, registered at positive potentials, showed two reversible redox couples at 0.80 V and 1.16 V vs. Fc/Fc^+ (Fig. 1b), which could be attributed to consecutive oxidations of two acridone moieties present in the molecule.^{1c,12b} It should be noted that the oxidation potential of **2** increases as compared to that of **QA-C8** (Fig. 1c), despite its extended conjugation. This effect is attributed to nonlinearity of the molecule's conjugated core which leads to more difficult oxidation as observed earlier for similar compounds.¹³

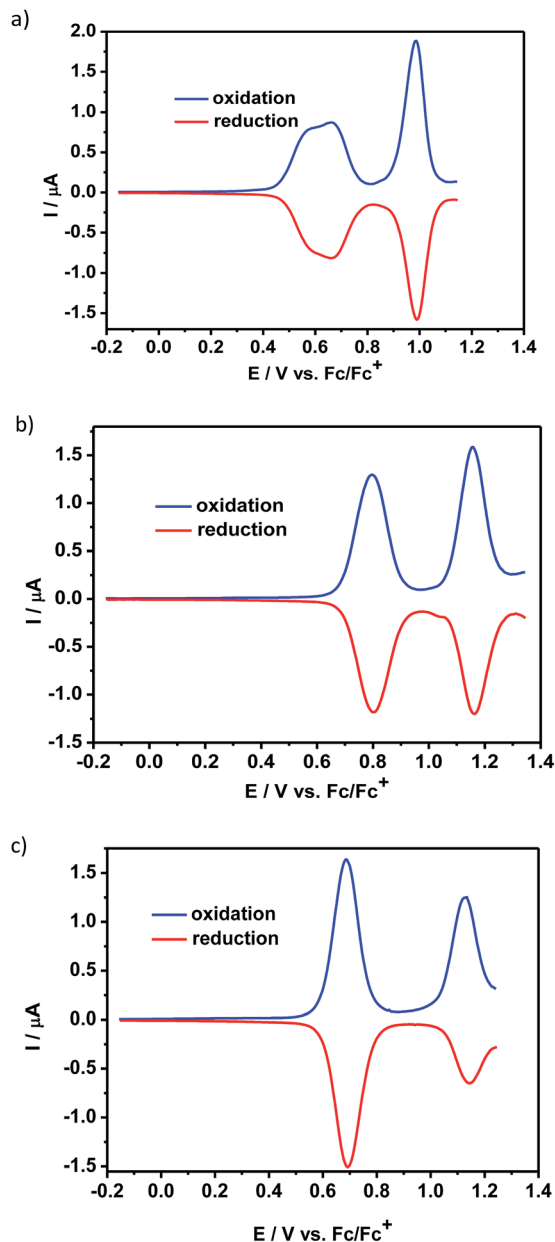

Fig. 1 Differential pulse voltammograms – oxidation mode: (a) **1**, (b) **2**, (c) **QA-C8** in CH_2Cl_2 solution (the concentration of the compounds was $c = 10^{-3}$ M) containing an electrolyte – 0.1 M Bu_4NBF_4 .

The reduction processes of **1** and **2** were significantly different. The CV of **1** (ESI, Fig. S6a†) displayed an irreversible process and its DPV curve could not be properly registered at such negative potentials. In contrast, the differential pulse voltammogram of **2** showed a reversible reduction peak at -2.08 V and an additional quasi-reversible one at -2.30 V vs. Fc/Fc^+ (Fig. 2a). These reduction peaks were shifted to lower potential values as compared to the corresponding peaks in the voltammogram of **QA-C8** registered in the same experimental conditions, *i.e.* -1.82 V and -2.17 V vs. Fc/Fc^+ (Fig. 2b).

From the formal potential of the first oxidation process it is possible to calculate the ionization potentials, IP, of **1** and **2** expressing their values with respect to a vacuum level, whereas

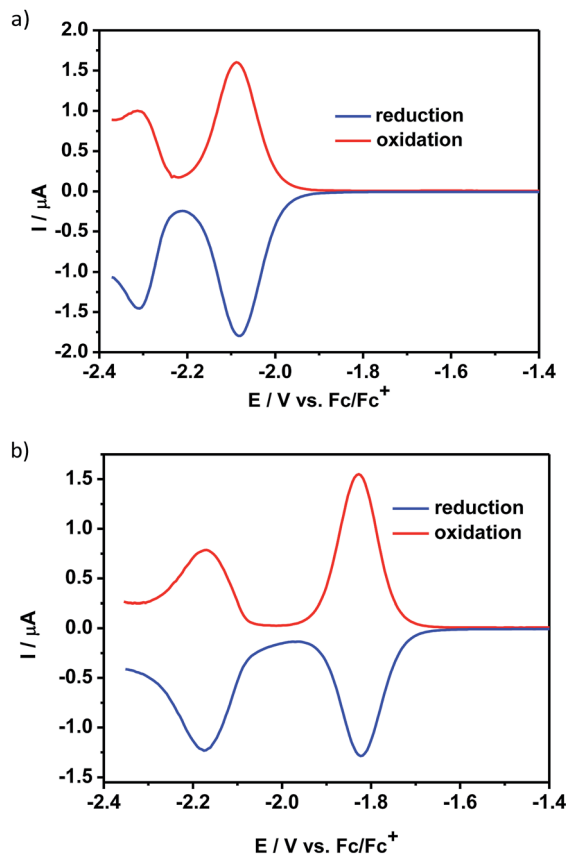

Fig. 2 Differential pulse voltammograms – reduction mode: (a) **2**, (b) **QA-C8** in CH_2Cl_2 solution (the concentration of the compounds was $c = 10^{-3}$ M) containing an electrolyte – 0.1 M Bu_4NBF_4 .

Table 1 First oxidation and reduction potentials (vs. Fc/Fc^+), ionization potentials, IP, and electron affinities, EA, of quinacridone derivatives

Compound	E_{ox1}^0 [V]	E_{red1}^0 [V]	IP ^a [eV]	EA ^b [eV]
1	0.55	—	5.35	—
2	0.80	-2.08	5.60	-2.72
QA-C8	0.68	-1.82	5.48	-2.98

^a IP values were calculated according to the following equation: $\text{IP} = e(4.8 + E_{\text{ox1}}^0)$ eV. ^b EA values were calculated according to the following equation: $\text{EA} = -e(4.8 + E_{\text{red1}}^0)$ eV.

from the formal potential of the first reduction process – the electron affinity, EA could be calculated.¹⁴ The IP value of **QA-C8** is intermediate between those calculated for **1** and **2** (Table 1). The EA value of **2** (Table 1) is higher by *ca.* 0.25 eV than that for **QA-C8**. This trend is clearly reflected in quantum chemical calculations (compare Table 2).

DFT calculations

The electronic structures of the new quinacridone derivatives were calculated using the *Gaussian09 Revision E.01* package and employing hybrid B3LYP exchange correlation potential combined with 6-31G(d,p) basis set.

Table 2 DFT calculations of the compounds **1**, **2**, QA-C8^a

Compound	Conditions	HOMO [eV]	LUMO [eV]	E_g [eV]	IP [eV]	EA [eV]
1	vac.	−5.08	−1.40	3.68	6.05	−0.32
	DCM	−5.21	−1.63	3.59	5.15	−1.70
2	vac.	−5.20	−1.84	3.37	6.32	−0.73
	DCM	−5.39	−2.07	3.32	5.35	−2.17
QA-C8	vac.	−5.17	−2.08	3.09	6.35	−0.90
	DCM	−5.29	−2.29	3.00	5.25	−2.36

^a Calculated energies of HOMO and LUMO orbitals, the band gap, E_g , ionization potential, IP, and electron affinity, EA, (calculated at the B3LYP/6-31G(d,p) level of theory in vacuum and in DCM solvent for quinacridone derivatives).

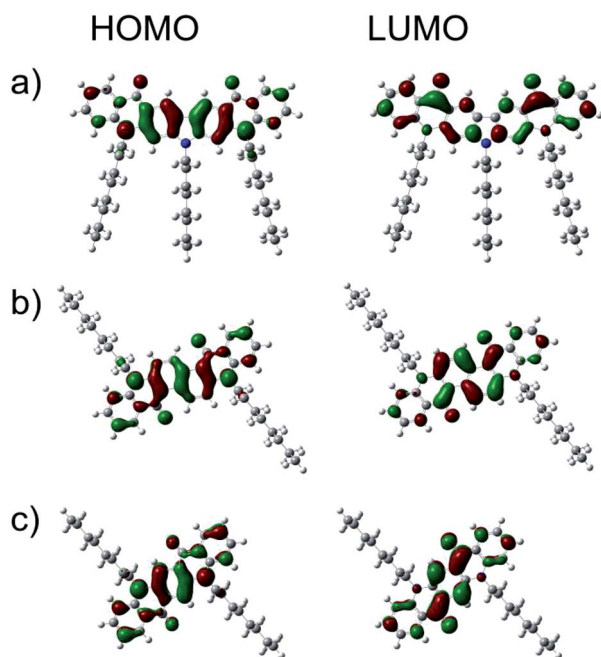

Fig. 3 HOMO and LUMO contours for compounds **1** (a), **2** (b) and QA-C8 (c) calculated at B3LYP/6-31G(d,p) level of theory (isosurface value: 0.03 green and red stand for negative and positive value, respectively).

Fig. 3 shows that both HOMO and LUMO were located on whole π -systems. The calculated HOMO energy levels of **1** and **2** were very close to that of QA-C8 (Table 2). However, the LUMO level of **1** was far above the LUMO levels calculated for **2** and QA-C8, which is in agreement with the electrochemical measurements. The DFT calculations demonstrated also that the solvation changes the HOMO/LUMO levels, dropping down both values by *ca.* 0.2 eV. The calculated IP values were *ca.* 0.2 eV smaller than those derived from the cyclic voltammetry investigations, however, the trend remains the same.

X-ray diffraction studies

The crystal structure of **2** was determined at RT by X-ray diffraction (ESI, Table S1†).¹⁵ **2** crystallizes in the $P2_1/c$ space group with half a molecule in the asymmetric unit.

The molecules of **2** (the structure in Fig. 4) are centrosymmetric (C_i point group) and consist of a flat aromatic core and *n*-

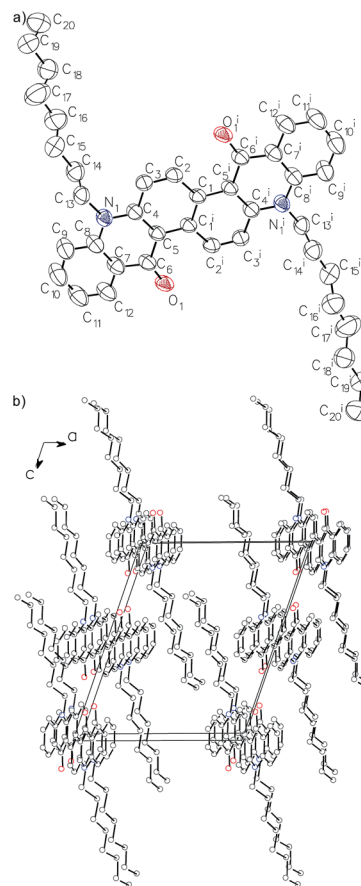

Fig. 4 Molecular structure (a) and ball-and-stick model of crystal packing (b) of compound **2**. Only the major part of the disordered *n*-octyl groups is shown. Thermal ellipsoids drawn at 50% level (a) and hydrogen atoms omitted for clarity. $i = -x, -y, -z$.

octyl groups with disordered terminal carbon atoms (C18, C19 and C20). There are two intramolecular C–H \cdots O hydrogen bonds between oxygen atoms of carbonyl groups and hydrogen atoms of the aromatic core ($d(C2\cdots O1^i) = 2.770(2)$ Å, $d(H2\cdots O1^i) = 2.09$ Å, $C2-H2\cdots O1^i = 129^\circ$, $i = -x, -y, -z$). Molecules are arranged by π stacking into columns running along the crystallographic Y axis. The distance between aromatic core planes of adjacent molecules in columns is $3.4793(12)$ Å. The columns are held together in the 3D crystal structure by dispersion interactions between interdigitated alkyl chains and

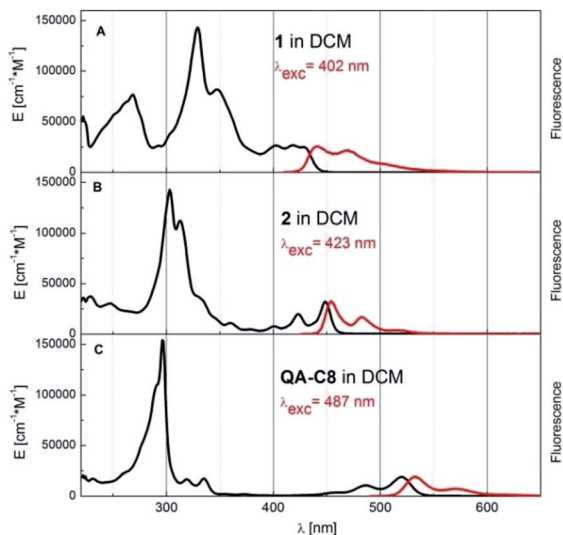

Fig. 5 Absorption (black curve, given in the extinction units) and fluorescence (red, arbitrary units) spectra of compounds **1**, **2** and **QA-C8** in dichloromethane (DCM) at room temperature.

by C–H...O interactions ($d(\text{C3}\cdots\text{O1}^{\text{ii}}) = 3.352(2) \text{ \AA}$, $d(\text{H3}\cdots\text{O1}^{\text{ii}}) = 2.56 \text{ \AA}$, $\text{C3}–\text{H3}\cdots\text{O1}^{\text{ii}} = 144^\circ$, $\text{ii} = x, 1/2 - y, 1/2 + z$).

Optical studies

Modification of the conjugated core in **1** and **2** led to profound changes in their optical properties as compared to the case of **QA-C8**. The UV-Vis absorption and fluorescence spectra of these three compounds are compared in Fig. 5. A clear hypsochromic shift of the absorption and the emission bands of **1** and **2** with respect to the corresponding bands of **QA-C8** is observed (by 102 nm and 91 nm for **1** and 71 nm and 79 nm for **2**) (ESI, Table S2[†]) again consistent with quantum chemical calculations. These significant hypsochromic shifts reflect the influence of the modification of the central aromatic core on optical properties of new derivatives and allow to displace the emission towards the blue-yellow range.

The naphthalene derivative **2** is especially interesting for potential optoelectronic applications, for which a very small Stokes shift between the absorption and fluorescence bands maxima was observed. Furthermore, this compound is a very good emitter of fluorescence photons, much better than **QA-C8** (see ESI Table S2[†] and the spectroscopic data of quinacridone reported previously^{16,16,17}). The fluorescence quantum yield of **2** is pretty high 0.83 and the lifetime as short as 0.92 ns, which results in very high radiative rate constant $k_r = 90.2 \times 10^7 \text{ s}^{-1}$.

Conclusions

In summary, we have demonstrated that the palladium catalyzed C–N coupling reaction can be applied for the synthesis of new quinacridone derivatives and allows the incorporation of moieties other than phenylene ring into the central core of the molecule, which can influence the electronic, optical and electrochemical properties of these new compounds. Two new

quinacridone derivatives were prepared and characterized by electrochemical and optical studies. Furthermore, the compound **2** with the naphthalene central core is a very good emitter of fluorescence photons, much better than classical quinacridone. The synthesized new molecules are promising candidates for optoelectronics.
