# Synthesis of In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures for near room temperature ethanol sensing†

Yujie Li,‡ Hongru Yang,‡ Jian Tian,\* Xiaolin Hu and Hongzhi Cui\*

In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures are prepared *via* a facile hydrothermal strategy. Plenty of smaller In<sub>2</sub>O<sub>3</sub> nanoparticles are uniformly deposited onto the surface of TiO<sub>2</sub> nanobelts. Compared with pure TiO<sub>2</sub> nanobelts and In<sub>2</sub>O<sub>3</sub> nanoparticles, the obtained In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures exhibit enhanced ethanol sensing properties at a temperature as low as 45 °C and a low detection limit (1 ppm). The improved sensing properties are mainly attributed to the synergic effect of fast charge transfer of heterostructure and the formation of preferential adsorption sites by the small size of the In<sub>2</sub>O<sub>3</sub> nanoparticles.

## Introduction

The growing concerns related to safety in residential areas resulted in the rapid development of the effective detection of toxic and hazardous gases.<sup>1,2</sup> As an important direct semiconductor with a band gap of 3.2 eV, TiO<sub>2</sub> has been applied in many fields of research, including solar cells,<sup>3</sup> Li-ion batteries,<sup>4</sup> photocatalysis,<sup>5</sup> photoelectrochemical cells,<sup>6</sup> and sensors,<sup>7</sup> due to its low cost and power consumption, ease of fabrication and use, stability in harsh environments, *etc.* Nanostructured TiO<sub>2</sub> is generally considered a remarkable candidate for gas sensors. However, the development of near room temperature/low detection limit gas sensors remains a challenge.

There are two common strategies that have been pursued in the literature to improve the properties of gas sensors.<sup>8</sup> One

method is controlling the growth of TiO<sub>2</sub> with a specially designed shape and morphology, such as one-dimensional (1D) TiO<sub>2</sub> nanobelts.<sup>9</sup> Previous results have demonstrated that TiO<sub>2</sub> nanobelts are highly advantageous for use in chemical sensors comparing with their thin-film or bulk counterparts because of their high surface-to-volume ratio, controllable structure and facile electron transport in materials.<sup>10</sup> The other method is surface modification with semiconductor oxides, such as ZnO,<sup>11</sup> In<sub>2</sub>O<sub>3</sub>,<sup>12</sup> and Sn<sub>3</sub>O<sub>4</sub>,<sup>8</sup> to construct heterostructure. In gas sensing, the heterostructure acts as a lever in electron transfer, through which electron transfer is facilitated or restrained, resulting in the enhanced sensing properties of the sensor.

It is generally difficult for a gas sensor based on a single oxide semiconductor to satisfy all requirements on sensor response, selectivity, stability, and working temperature. Sensors based on two or more components have been explored to improve gas sensing performance.<sup>13</sup> Among the various oxides, 1D TiO<sub>2</sub>, such as TiO<sub>2</sub> nanobelt, is a promising candidate as the backbone for the design and fabrication of composite nanostructures.<sup>14</sup> Indium oxide (In<sub>2</sub>O<sub>3</sub>), an n-type indirect band semiconductor with an indirect band gap of 2.8 eV, has been recognized as the potential sensing material due to its high electric conductance.<sup>15</sup> Other studies also show that In<sub>2</sub>O<sub>3</sub> has high sensitivities to many gases such as H<sub>2</sub>,<sup>16</sup> CO,<sup>12</sup> NO<sub>2</sub>,<sup>17</sup> NH<sub>3</sub>,<sup>18</sup> O<sub>3</sub>,<sup>19</sup> and Cl<sub>2</sub>.<sup>20</sup> In particular, In<sub>2</sub>O<sub>3</sub>-based sensors have been reported to be highly selective to ethanol gas.<sup>15</sup> However, the In<sub>2</sub>O<sub>3</sub> nanoparticles have limited sensing activity due to the presence of fewer active surface sites inducing by aggregation. So In<sub>2</sub>O<sub>3</sub> nanoparticles need to be well dispersed on the support to achieve high mass activity and resistance to aggregation. TiO<sub>2</sub> nanobelts possess a large surface area, and can provide sufficient space for the nucleation and growth of In<sub>2</sub>O<sub>3</sub> nanoparticles on their surfaces. As motivated by the driving force of developing nanomaterials with

enhanced sensing performance, great efforts have been exhausted on the design of  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures.

In this work, a novel heterostructure made of  $\text{TiO}_2$  nanobelt backbones and small size of well-dispersed  $\text{In}_2\text{O}_3$  nanoparticles is prepared by a facile hydrothermal method. Compared to pristine  $\text{TiO}_2$  nanobelts and  $\text{In}_2\text{O}_3$  nanoparticles, a near room temperature (45 °C)/low detection limit (1 ppm) gas sensing performance enhancement of  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures is first documented. The  $\text{TiO}_2$  nanobelt substrates restrict the growth of  $\text{In}_2\text{O}_3$  nanoparticles, resulting in the formation of smaller  $\text{In}_2\text{O}_3$  nanoparticles with more interaction sites for analytic gases. This remarkable property can be attributed to the combination of several factors, including efficient electron separation of heterostructure, increased surface active sites of  $\text{In}_2\text{O}_3$  nanoparticles with small size, and the large surface area.

## Materials and methods

### Materials

Titania P25 ( $\text{TiO}_2$ ), sodium hydroxide ( $\text{NaOH}$ ), hydrochloric acid ( $\text{HCl}$ ), sulfuric acid ( $\text{H}_2\text{SO}_4$ ), indium nitrate hydrate ( $\text{In}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$ ), carbamide ( $\text{CO}(\text{NH}_2)_2$ ), diethylene glycol (DEG), and ethanol were purchased from Sinopharm.

### Synthesis

**Preparation of  $\text{TiO}_2$  nanobelts.**  $\text{TiO}_2$  nanobelts were synthesized by a hydrothermal procedure. Typically, P25 powder (0.1 g) was mixed with an aqueous solution of  $\text{NaOH}$  (20 mL 10 M), followed by a hydrothermal treatment at 180 °C in a 25 mL Teflon-lined autoclave for 72 h. The treated powder was washed thoroughly with deionized water followed by filtration and drying processes. The obtained  $\text{Na}_2\text{Ti}_3\text{O}_7$  nanobelts were then immersed in an aqueous solution of 0.1 M  $\text{HCl}$  for 48 h to obtain  $\text{H}_2\text{Ti}_3\text{O}_7$  nanobelts. The above products were dissolved in a 0.02 M  $\text{H}_2\text{SO}_4$  solution and maintained at 100 °C for 6 h. Finally, the products were isolated from solution by centrifugation and sequentially washed with deionized water several times by filtration, and dried at 60 °C for 10 h. Thermal annealing of the  $\text{H}_2\text{Ti}_3\text{O}_7$  nanobelts by acid corrosion at 600 °C for 2 h led to production of  $\text{TiO}_2$  nanobelts with roughened surfaces.

**Preparation of  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures (mole ratios at 1 : 2, 1 : 1 and 2 : 1).** First,  $\text{In}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$  (73.3–293 mg) and  $\text{CO}(\text{NH}_2)_2$  (1 g) were dissolved in the mixture of 13 mL of diethylene glycol and 2 mL of  $\text{H}_2\text{O}$  under magnetic stirring. The  $\text{TiO}_2$  nanobelts (15 mg) were dispersed in above solution with magnetically stirring for 2 h, and the final pH 6.5, then transferred into a 20 mL Teflon-lined stainless autoclave, sealed and maintained at 200 °C for 24 h. The as-fabricated products were collected out and washed several times with ethanol and deionized water by filtration, respectively. After drying at 60 °C for 12 h, the  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures (mole ratios at 1 : 2, 1 : 1 and 2 : 1) were obtained. For comparison, pure  $\text{In}_2\text{O}_3$  nanoparticles were

also synthesized in the same manner without the addition of  $\text{TiO}_2$  nanobelts.

**Characterization.** X-ray powder diffraction (XRD) patterns were recorded with a Bruke D8 Advance powder X-ray diffractometer with  $\text{Cu K}\alpha$  ( $\lambda = 0.15406$  nm). Scanning electron microscopy (SEM) was performed with a FEI NanoSEM 450 instrument with an energy-dispersive X-ray spectroscopy (EDS). High resolution transmission electron microscopy (HRTEM) images were carried out with a JOEL JEM 2100F microscope. SEM and TEM samples were prepared by a drop casting method with 1 mg  $\text{mL}^{-1}$  ethanol solution of  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures. X-ray photoelectron spectroscopy (XPS) was performed using an ESCALAB 250. The specific surface area was calculated using the Brunauer–Emmett–Teller (BET) method using the measurement instrument (Micromeritics, ASAP2020). The zeta potential of the samples suspended in deionized water was measured using a zeta potentiometer (Zetapals, Brookhaven).

**Sensing tests.** The gas sensing properties of as prepared  $\text{TiO}_2$  nanobelts,  $\text{In}_2\text{O}_3$  nanoparticles and  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures were tested on a WS-30A gas sensing instrument (WeiSheng Electronics Co., Ltd., Henan, China). The fabrication and testing principle of gas sensors referred to previous works.<sup>21</sup> The response of the samples was defined as the ratio of  $R_a/R_g$ , where  $R_a$  and  $R_g$  are the electrical resistance of the sensor in air and in the presence of the test gas mixed in air, respectively.

## Results and discussion

XRD analysis associated with  $\text{TiO}_2$  nanobelts,  $\text{In}_2\text{O}_3$  nanoparticles and  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures is performed to investigate the crystal structure and purity of the samples, which is shown in Fig. 1. For  $\text{TiO}_2$  nanobelts (curve a), eight distinctive peaks at  $2\theta = 25.3^\circ, 37.8^\circ,$

Fig. 1 XRD patterns of (a)  $\text{TiO}_2$  nanobelts, (b)  $\text{In}_2\text{O}_3$  nanoparticles, and (c)  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures (mole ratio 1 : 1).

48.1°, 53.9°, 55.1°, 62.7°, 68.8°, and 76.0° match well with anatase TiO<sub>2</sub> (JCPDS 21-1272).<sup>22</sup> At the same time, the TiO<sub>2</sub>(B) phase appears in the sample. The peak sites of TiO<sub>2</sub>(B) locate at 14.2°, 28.5° and 43.5° (JCPDS 46-1237).<sup>23</sup> As shown in curve (b), the crystal phase of In<sub>2</sub>O<sub>3</sub> nanoparticles with the diffraction peaks at about  $2\theta = 22.4^\circ, 30.9^\circ, 32.6^\circ, 37.7^\circ, 45.6^\circ, 50.3^\circ, 54.1^\circ, 57.2^\circ, 58.2^\circ$  and  $68.4^\circ$ , which could be perfectly indexed to the (012), (104), (110), (113), (024), (116), (018), (214), (300) and (220) crystal faces of cubic In<sub>2</sub>O<sub>3</sub> crystalline phase (JCPDS 71-2194).<sup>24</sup> For In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures (curve c), all the peaks can be assigned to TiO<sub>2</sub> or In<sub>2</sub>O<sub>3</sub>, with no extra peaks observed, which demonstrates the high purity of the samples.

The size and morphology of samples were investigated by scanning electron microscopy (SEM), as exhibited in Fig. 2 and S1.† The as-obtained TiO<sub>2</sub> nanobelts are around 200 nm in width, 20–40 nm in thickness, and several micrometers in length<sup>25</sup> (Fig. S1a†). After the acid etching process, the surface-coarsened TiO<sub>2</sub> nanobelts are obtained (Fig. S1b and c†), which have a large specific surface area and can offer abundant nucleation sites for the deposition of In<sub>2</sub>O<sub>3</sub> nanoparticles.<sup>10</sup> Fig. 2a reveals an agglomeration of individual In<sub>2</sub>O<sub>3</sub> nanoparticles. The successful formation of In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures is confirmed by the SEM image (Fig. 2b). The TiO<sub>2</sub> nanobelts are homogeneously covered by numerous In<sub>2</sub>O<sub>3</sub> nanoparticles with several nanometers in size. It is the coarsened surface of TiO<sub>2</sub> nanobelts that prevents In<sub>2</sub>O<sub>3</sub> nanoparticles forming aggregation in the reaction procedure. The formed heterostructure can improve the efficiency of interfacial charge separation and enhance the gas sensing activity.<sup>26</sup> Besides, the very small size of the In<sub>2</sub>O<sub>3</sub> nanoparticles could lead to highly sensitive sensors because of the high sensing surface.<sup>27</sup> EDS mapping (Fig. S2†) also shows that In, Ti, and O elements are found in the In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures, and no other impurities are observed.

N<sub>2</sub> isotherms adsorption–desorption curves are used to determine specific surface areas (Fig. S3†). The In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures with rough surface generally have a higher specific surface area (43.357 m<sup>2</sup> g<sup>-1</sup>) than In<sub>2</sub>O<sub>3</sub> nanoparticles (39.356 m<sup>2</sup> g<sup>-1</sup>) and TiO<sub>2</sub> nanobelts (32.767 m<sup>2</sup> g<sup>-1</sup>), which is favorable for gas detection. The large contact area can provide more reaction surface between heterostructure and target gas, resulting in the enhancement of gas sensing performance.

Fig. 2 SEM image of (a) In<sub>2</sub>O<sub>3</sub> nanoparticles and (b) In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures (mole ratio 1 : 1).

Fig. 3 shows the typical TEM images of In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures. It can be seen that the In<sub>2</sub>O<sub>3</sub> nanoparticles with size of *ca.* 10–15 nm are attached on the surface of TiO<sub>2</sub> nanobelts (Fig. 3a and b), coinciding with the results from the SEM observations. The crystalline lattice for the nanoparticle displays a *d*-spacing of approximately 0.29 nm, which corresponds to the interplanar spacing of the (222) planes of cubic In<sub>2</sub>O<sub>3</sub> (Fig. 3c).<sup>28</sup> In addition, the spacing of the fringes in the brighter region are 0.35 nm, which are assigned to the interplanar spacing of the (110) planes of TiO<sub>2</sub> (Fig. 3c).<sup>29</sup> The HRTEM images (Fig. 3c) clearly confirm that the In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructure has been fabricated successfully through as-adopted hydrothermal strategy. Such a close contact is expected to favor an efficient charge transfer between In<sub>2</sub>O<sub>3</sub> and TiO<sub>2</sub>, inducing a faster response of the sensor.

The XPS measurement of In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures is performed to further confirm the chemical composition and oxidation state, and the results are shown in Fig. 4. The fully scanned spectrum of In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures suggests that the sample consists of In, Ti, O and C, as shown in Fig. 4a. The elements of In, Ti, and O belong to the In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructure. The peak for C 1s at 284.8 eV is ascribed to adventitious carbon from the XPS instrument.<sup>30</sup> The XPS spectrum (Fig. 4b) for Ti 2p shows two peaks at 464.2 and 458.5 eV that are assigned to Ti 2p<sub>1/2</sub> and Ti 2p<sub>3/2</sub> respectively, which is a characteristic of Ti<sup>4+</sup> in TiO<sub>2</sub>.<sup>31</sup> The In 3d XPS spectrum (Fig. 4c) consists of two peaks centered at 452.5 and 444.5 eV for the 3d<sub>3/2</sub> and 3d<sub>5/2</sub> peaks, respectively, corresponding to the In<sup>3+</sup> spectrum in In<sub>2</sub>O<sub>3</sub>.<sup>32</sup> The O 1s spectrum shows three peaks at 529.6, 531.2 and 532.0 eV, as shown in Fig. 4d. Here, the intense peaks at 529.6 and 531.2 eV can be assigned to lattice oxygen in TiO<sub>2</sub> and In<sub>2</sub>O<sub>3</sub> species, whereas the weak peak at 532 eV is possibly related to the adsorbed oxygen.<sup>33</sup> All of these results give the insight that the In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures are composed of In<sub>2</sub>O<sub>3</sub> and TiO<sub>2</sub>. Moreover, the In 3d peaks in the In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures shift toward the higher binding energies as compared with those of pure In<sub>2</sub>O<sub>3</sub>, while lower binding energies of Ti 2p from TiO<sub>2</sub> are observed in the heterostructure (Fig. S4†). These phenomena can be explained by partial electron transfers from In<sub>2</sub>O<sub>3</sub> to TiO<sub>2</sub>, *i.e.*, an increase (decrease) of the electron density of TiO<sub>2</sub> (In<sub>2</sub>O<sub>3</sub>) leads to the reduction (enhancement) of the binding energies of Ti 2p (In 3d). From the XPS results, we can expect the strong interfacial coupling effect between In<sub>2</sub>O<sub>3</sub> and TiO<sub>2</sub>, which could promote the electron transfer and further enhance the gas sensing performance of In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures.

Fig. 3 (a and b) TEM and (c) high-magnification TEM images of In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures (mole ratio 1 : 1).

Fig. 4 XPS spectra of  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures (mole ratio 1 : 1): (a) fully scanned spectra, (b) Ti 2p, (c) In 3d, and (d) O 1s.

The schematic of the ethanol gas sensor is shown in Fig. 5a. The relationship between the operating temperature and gas responses to 100 ppm ethanol of the three kinds of sensor devices were first investigated in the temperature range of 45–440 °C (Fig. 5b and S5†). Since the target gas molecules are not active enough to overcome the activation energy barrier to react with the surface-absorbed oxygen species at a low temperature,<sup>34–37</sup> while at temperatures that are too high and difficult in gas adsorption, in turn cause the low utilization rate of the sensing material; thus, low gas responses are achieved in both of two situation.<sup>38</sup> Hence, an “increase-maximum-decay” tendency is obtained along with the temperature increasing. More noticeable, it can be seen that  $\text{TiO}_2$  nanobelts,  $\text{In}_2\text{O}_3$  nanoparticles, and  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures share the same optimal operating temperature at about 400 °C. The sensor response of the pure  $\text{TiO}_2$  nanobelts and  $\text{In}_2\text{O}_3$  nanoparticles is only 10.2 and 63.8, respectively at 400 °C. The response of the sensor based on  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures reaches a maximum value of 106.3 at 400 °C, which was 1.67 times and 10.4 times higher than that of  $\text{In}_2\text{O}_3$  nanoparticles and  $\text{TiO}_2$  nanobelts, respectively. Even at operating temperature as low as 100 °C (Fig. 5b), the sensitivity of the  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures reaches to about 13, which is much higher than

Fig. 5 (a) Schematic of the ethanol gas sensor; (b) variation of response ( $R_a/R_g$ ) with working temperature of the three different kinds of sensors based on  $\text{TiO}_2$  nanobelts,  $\text{In}_2\text{O}_3$  nanoparticles, and  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures (mole ratio 1 : 1) to 100 ppm ethanol vapor.

those listed in literatures.<sup>39,40</sup> Moreover, the  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures still have response even at near room temperature (45 °C) (Fig. S5†). To the best of our knowledge, this remarkable response to ethanol and selectivity at 45 °C has never reported before for an  $\text{In}_2\text{O}_3$  based sensor. Thus, it is a proof of concept that  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures can be used as selective sensor at near room temperature.

The dynamic responses of  $\text{TiO}_2$  nanobelts,  $\text{In}_2\text{O}_3$  nanoparticles and  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures under different concentration from 1 ppm to 100 ppm of ethanol at an optimal operating temperature of 400 °C are revealed in Fig. 6. It can be seen that the corresponding responses of the sensors are highly dependent on the concentration of ethanol. The sensor made from the  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures even shows a higher response (21) at 10 ppm, which is better than that of  $\text{TiO}_2$  nanobelts and  $\text{In}_2\text{O}_3$  nanoparticles, indicating the good sensing capability to ethanol (Fig. 6a–c). Impressively, the  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures still have the response at the very low concentration of 1 ppm (Fig. 6d).

From the perspective of practical application of sensor device, not only high response but also fast response speed should be paid attention to, on account of their vital roles on avoiding possible loss and disasters. The dynamic response curve shown in Fig. 6a–c demonstrates the  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures exhibit excellent response and recovery capability toward 100 ppm ethanol. The response time of  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures to 100 ppm ethanol is as low as 6 s, which is far less than that of  $\text{In}_2\text{O}_3$  nanoparticles (9 s) and  $\text{TiO}_2$  nanobelt (21 s). Meanwhile, the recovery time of the  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures,  $\text{In}_2\text{O}_3$  nanoparticles and  $\text{TiO}_2$  nanobelts are 3 s, 4 s and 45 s to 100 ppm ethanol, respectively. Therefore, the  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructure sensor

Fig. 6 Response curve and response profiles of ethanol vapor sensors based on (a)  $\text{TiO}_2$  nanobelts, (b)  $\text{In}_2\text{O}_3$  nanoparticles, and (c and d)  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures (mole ratio 1 : 1) upon exposure to different concentrations of ethanol vapor at an optimal operating temperature of 400 °C.

displays faster response and recovery speed than pristine  $\text{In}_2\text{O}_3$  nanoparticle and  $\text{TiO}_2$  nanobelt.

Since selectivity is a remarkable aspect of sensing properties. Fig. 7 reveals the response of the sensor that coating  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures to various kinds of test gases (acetone, benzene, ammonium hydroxide, ethyl acetate and ethanol) at 100 ppm. All of those gases are tested at a low temperature of 100 °C. Obviously, the response to ethanol is much higher than that of other probe analytes, suggesting good selectivity of as prepared  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures.

It should be noted that the sensing activity of  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures also depend on the  $\text{In}_2\text{O}_3$  :  $\text{TiO}_2$  molar ratio, as shown in Fig. 7. All of the  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures at different mole ratios present excellent response to ethanol at a low temperature of 100 °C, which can be explained that the high dispersed  $\text{In}_2\text{O}_3$  nanoparticles on the surface of  $\text{TiO}_2$  nanobelts will have good sensing activity. The optimal molar ratio of  $\text{In}_2\text{O}_3$  :  $\text{TiO}_2$  is 1 : 1. The  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures at mole ratio (1 : 2) exhibit lower ethanol response due to the less amount of  $\text{In}_2\text{O}_3$  and low number of junctions with  $\text{TiO}_2$  nanobelts. Moreover, the  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures at mole ratio (1 : 1) present higher ethanol response than that of  $\text{In}_2\text{O}_3/\text{TiO}_2$  mole ratio (2 : 1). This should be caused that excessive  $\text{In}_2\text{O}_3$  nanoparticles cover the active sites of  $\text{TiO}_2$  nanobelts, which hinder the electron transfer on the interface of  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures, and thus in turn inhibit the sensing activity.

The cyclic experiment on sensing performance of  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures proves that the heterostructures display excellent ethanol response stability even after 6 weeks (Fig. S6†).

Fig. 7 Response ( $R_a/R_g$ ) of  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures (mole ratio at 1 : 2, 1 : 1, and 2 : 1) sensor to acetone, benzene, ammonium hydroxide, ethyl acetate and ethanol vapor at 100 ppm with respect to a low temperature of 100 °C.

On the basis of the above results, a synergetic mechanism between  $\text{In}_2\text{O}_3$  nanoparticles and  $\text{TiO}_2$  nanobelts in the  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures for the enhanced gas sensing property is proposed (Fig. 8). The conduction band (CB) and valence band (VB) potentials of  $\text{In}_2\text{O}_3$  nanoparticles are estimated to be  $-0.63$  and  $+2.17$  eV, and the CB and VB of  $\text{TiO}_2$  nanobelts are at  $-0.4$  and  $+2.8$  eV, respectively (Fig. S7†).<sup>26,39–43</sup>

To further explain the mechanism of the reactions between  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures and the target gas ethanol, a rational model is proposed, as shown in Fig. 8a and b. It has been clearly revealed that the  $\text{In}_2\text{O}_3$  nanoparticles decorated  $\text{TiO}_2$  nanobelts nanostructure exhibit much better sensing performances than that of pure  $\text{In}_2\text{O}_3$  nanoparticles and  $\text{TiO}_2$  nanobelts, indicating the formation of heterostructure, which can contribute greatly to the improvement of sensing properties. The dramatic enhancement in sensing properties of  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures can be attributed to the following three factors.

First, the striking synergistic effect of the two metal oxides. For the as-prepared  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures, the surfaces of  $\text{TiO}_2$  nanobelts are not completely enclosed by  $\text{In}_2\text{O}_3$  nanoparticles, resulting in both of them being highly accessible for the adsorption of oxygen molecules and promoting the formation of depletion layers on the surfaces of both metal oxides while exposed to air.<sup>44–47</sup> Therefore, both  $\text{In}_2\text{O}_3$  nanoparticles and  $\text{TiO}_2$  nanobelts contribute to ethanol response.

Second, preparation of small and well-dispersed sensing materials is an effective manner to improve the sensor response. In the current work, well-dispersed  $\text{In}_2\text{O}_3$  nanoparticles are deposited onto the surface of  $\text{TiO}_2$  nanobelts through controlling pH = 6.5 to keep strong electrostatic attraction between  $\text{TiO}_2$  and  $\text{In}_2\text{O}_3$  (Fig. S8†). The  $\text{TiO}_2$  nanobelts can act as backbone for the nucleation and growth of  $\text{In}_2\text{O}_3$  nanoparticles,<sup>48</sup> and prevent the aggregation of  $\text{In}_2\text{O}_3$  nanoparticles. The smaller  $\text{In}_2\text{O}_3$  nanoparticles on the surface

Fig. 8 Model of the sensor based on  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures exposed in (a) air and (b) ethanol mixed air, respectively; (c and d) gas sensing mechanism of  $\text{In}_2\text{O}_3$  nanoparticle/ $\text{TiO}_2$  nanobelt heterostructures,  $E_c$ : conduction band,  $E_f$ : Fermi level and  $E_v$ : valence band.

of TiO<sub>2</sub> nanobelts have the exposure of more sensitive surfaces, and can serve as effective adsorption sites to bind and activate oxygen molecules. Thus, more absorbed oxygen species will diffuse to the surface of the sensing semiconductor, resulting in a larger degree of electron extractions from the conduction band of TiO<sub>2</sub> nanobelts. The high coverage of chemisorbed oxygen species make the In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures more sensitive to ethanol, directly resulting in a high response.

More importantly, owing to the strong electronic interaction between In<sub>2</sub>O<sub>3</sub> nanoparticles and TiO<sub>2</sub> nanobelts, a typical semiconductor junction was formed. The charge transport is significantly enhanced in the heterostructure, resulting in a rapid response–recovery.<sup>49</sup> So, the In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures are more sensitive to target gas and have superior properties.

Fig. 8c and d show the energy band diagram near the In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures. When the n-type semiconductor In<sub>2</sub>O<sub>3</sub> nanoparticles and n-type semiconductor TiO<sub>2</sub> nanobelts contact with each other, electrons would transfer from the CB of In<sub>2</sub>O<sub>3</sub> to the CB of TiO<sub>2</sub> until the Fermi energy levels ( $E_F$ ) of them become equal<sup>50</sup> (Fig. 8c). In ambient air, sensing materials can absorb oxygen molecules (O<sub>2</sub>) and form surface-adsorbed oxygen species (O<sub>2(ads)</sub><sup>-</sup>, O<sub>(ads)</sub><sup>-</sup>, and O<sub>(ads)</sub><sup>2-</sup>, eqn (1)–(4)) by capturing free electrons from the CB of In<sub>2</sub>O<sub>3</sub> nanoparticles. The reaction kinematics can be described as follows:<sup>25</sup>

In this process, a thick electron depletion layer formed on the surface area, resulting in a decrease of carrier concentration and increase of sensor resistance in coincidence.<sup>51</sup> When the sensor is exposed to ethanol, at a moderate temperature, the adsorbed oxygen species will take part in the reaction with these gas molecules to form CO<sub>2</sub> and H<sub>2</sub>O (eqn (5)). The reactions between reducing gases and the surface adsorbed oxygen species can be described as follows:

As a result, the electrons trapped in the ionized oxygen species are released back to the CB of In<sub>2</sub>O<sub>3</sub> nanoparticles (Fig. 8d), which eventually lead to the thickness of electron depletion layer decreases and lowering the measured resistance of the sensor.

## Conclusions

Unique 1D nanostructures of TiO<sub>2</sub> decorated with In<sub>2</sub>O<sub>3</sub> nanoparticles have been synthesized *via* a simple hydrothermal method. The TiO<sub>2</sub> nanobelt substrates restrict the growth of

In<sub>2</sub>O<sub>3</sub> nanoparticles, resulting in the formation of uniform and smaller In<sub>2</sub>O<sub>3</sub> nanoparticles with a high number of surface active sites. Notably, the obtained In<sub>2</sub>O<sub>3</sub> nanoparticle/TiO<sub>2</sub> nanobelt heterostructures exhibit a much higher sensitive toward ethanol at near room temperature of 45 °C and low detection limit of 1 ppm. The synergic effect of pronounced electron transfer of heterostructure, as well as the creation of active adsorption sites by the small size of In<sub>2</sub>O<sub>3</sub> nanoparticles result in an enhancement of gas response in terms of response, response/recovery time and selectivity toward ethanol.
