Construction of the oxaphenalene skeletons of mansonone F derivatives through C–H bond functionalization and their evaluation for anti-proliferative activities†

Novel mansonone F derivatives were conveniently synthesized via a key step of Ru(II)-catalyzed C–H functionalization to rapidly construct oxaphenalene skeletons. This synthetic procedure is sufficiently robust and flexible to offer both the generation of diverse mansonone F analogs and the scale-up synthesis of selected compounds. The structural formulas of all products were confirmed and characterized using spectral data. Most of the derivatives exhibited significant cytotoxicity against four tested human tumor cell lines *in vitro*.

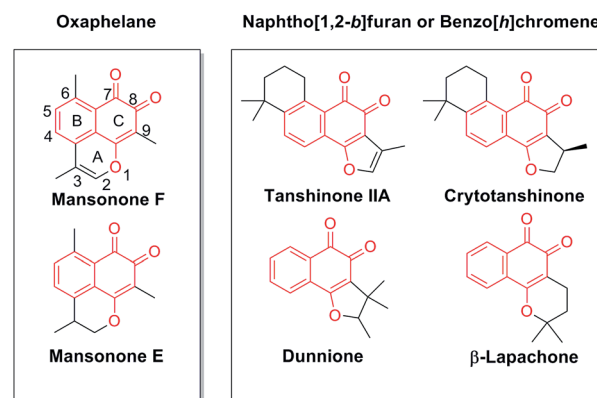

Introduction

Natural products have long been an important source of drugs or drug leads. Natural products or their derivatives still comprise more than 50% of the drugs that are used for cancer chemotherapy.¹ Many natural quinones and quinoid heterocycles have been reported to show antitumor effects. For example, tanshinone IIA,^{2,3} cryptotanshinone, dunnione, β -lapachone,^{4,5} and mansonone E and F^{6,7} show great potential as antitumor agents (Fig. 1). Unlike the common *o*-quinone compounds with structural features of naphtho[1,2-*b*]furan or benzo[*h*]chromene, mansonone F (Fig. 1, MsF), a tricyclic sesquiterpenoid naturally occurring as *ortho*-naphthoquinone with an unusual oxaphenalene skeleton, was first isolated from the heartwood of a west African tree *Mansonia altissima* A. Chev. (*Sterculiaceae*).^{8–10} MsF is a natural phytoalexin and MsF derivatives have attracted considerable attention because of their significant antimicrobial, antifungal, antioxidant, larvicidal and anticancer activities.^{11,12}

To date, several approaches for synthesizing MsF and its derivatives have been reported. For instance, intramolecular Diels–Alder addition of benzynes to furans and intramolecular Friedel–Crafts acylation has been utilized for this purpose.¹³ Based on the regioselective hydrolysis of a hydroquinone diacetate and IBX (2-iodoxybenzoic acid) as oxidant for the MsF,¹⁴ the oxaphenalene skeleton of MsF has also been constructed by

peri ring closure of naphthol ether.^{15,16} However, these multi-step synthetic routes are generally time-consuming as they present inherent structural constraints that limit further optimization of their biological properties through structural modification. Furthermore, the existing routes are hampered by low efficiency in constructing the parent rings. Therefore, development of a new synthetic route for biologically active MsF derivatives is necessary. A novel synthetic route for modification via a key step of Ru(II)-catalyzed C–H functionalization has also been used to construct the oxaphenalene skeleton and shorten previously used synthetic routes.^{17,18} Oxidative C–H bond functionalization provides economical access to important bioactive heteroarenes and thus has been extensively used in medicinal chemistry.¹⁹

In this study, a series of highly active derivatives were successfully synthesized by establishing a novel and efficient

synthetic route for MsF derivatives. The method is convenient and a one-step reaction is sufficient to construct the key tricyclic oxaphenylene intermediate using $C(sp^2)$ -H activation through Ru(II)-catalyzed cyclization. The synthesized compounds were then evaluated for their anti-proliferative activities with different cancer cell lines *in vitro*.

Results and discussion

Chemistry

The starting material, 1-naphthol, was treated with hex-3-yne in anhydrous dimethylformamide (DMF) with $[RuCl_2(p\text{-cymene})]_2$ as a catalyst and $Cu(OAc)_2 \cdot H_2O$ to obtain the key tricyclic oxaphenylene intermediate (Table 1, entry 1). Furthermore, the reactivity of the *o*-substituted 1-naphthol was investigated. *o*-Chloro-1-naphthol has low yield of 30% when $(Cp^*RhCl_2)_2$ was used as catalyst (Table 1, entry 9). We found that *o*-methyl, *o*-bromo or *o*-nitro naphthol could not form the oxaphenylene structure even under 150 °C and under the presence of $RhCp^*(CH_3CN)(SbF_6)_2$ (Table 1, entries 2–7 and 10–18). Ortho-substituents have a large steric hindrance effect on the cyclization reactivity. In addition, the reaction yield of 4-nitro-1-naphthol is higher than that of 1-naphthol (Table 1, entry 19). The reason is that the presence of electron-withdrawing groups leads to the stronger acidity of phenols and the easier dissociation of phenoxy anions. Thus, 4-nitro-1-naphthol was used as the starting substrate and $[RuCl_2(p\text{-cymene})]_2$ as the catalyst to

prepare the oxaphenylene intermediates. Introduction of substituent groups is the optimal strategy to synthesize Msn derivatives. The reactivity of different alkynes was also investigated in this cyclization reaction. The result showed that only alkyl or aromatic alkynes can participate in the reaction (Table 2, entries 1–15). Aromatic substituted alkynes illustrate an easier reaction with higher yield and faster speed than that of alkyl alkynes (Table 2, entries 4–12). Interestingly, the terminal and TMS-protected alkynes could not afford the expected product in this catalytic system (Table 2, entries 22 and 23).

The proposed MsF derivatives were obtained as outlined in Scheme 1 and 2.²⁰ The key tricyclic oxaphenylene intermediate **2** was constructed through a one-step Ru(II)-catalyzed cyclization reaction based on the above optimized conditions. The two subsequent steps were performed according to a previously described method with minor modification.⁷ The nitro group of intermediate **2** was reduced to amine by using sodium hydro-sulfite as the reducing reagent. The amine was oxidized by Fremy's salt, thereby generating target compounds **3** (Scheme 1).

MsF derivatives substituted at the C-9 position were obtained from **3a** to **3f** *via* different methods. Fluoro-substituted MsF derivatives **4** were obtained by using Selectfluor®. Meanwhile, chloro- and bromo-substituted MsF derivatives **5** and **6** were obtained by using *N*-chlorosuccinimide and *N*-bromosuccinimide,

respectively. Nitro-substituted MsF derivatives **7** were obtained by using cupric nitrate (Scheme 1).

Furthermore, 4,5-disubstituted MsF derivatives were synthesized from 6,7-difluoronaphthalen-1-ol **10**. However, given that it is not commercially available, the starting 1-bromo-2,4,5-

trifluorobenzene **8** was treated with Mg in anhydrous THF. Afterward, furan was added *via* Diels–Alder cyclization to obtain 6,7-difluoro-1,4-dihydro-1,4-epoxynaphthalene **9**.^{21,22} The O-ring opening of **9** was created by adding BF_3 -etherate in dichloromethane obtaining 6,7-difluoronaphthalen-1-ol **10**. For the compounds with 6,7-difluoro group, the yield in the C–H functional step was improved from 10% to 45% (Table 3) when *m*-xylene was used as solvent instead of DMF. The 5-amination products **15** were produced by treating **12** with various amine and K_2CO_3 in DMF. Based on the information of NOESY spectra of compound **17**, both 6-H ($\delta = 7.79$ ppm) and piperidyl $\alpha\text{-CH}_2$ ($\delta = 3.23$ ppm) have a through-space correlation. Piperidyl should be considered only as a 5-position substituent group. This finding is possibly due to the C-5 position having lower steric hindrance and higher electron density than the C-4 position, which makes electrophilic substitution more likely at the C-5 position. As shown in Scheme 2, target compounds **13** and **16a–16d** were obtained by using the strategy mentioned in Scheme 1, whereas **13** and **16a** were brominated by using *N*-bromosuccinimide in carbon tetrachloride to obtain **14** and **17**, respectively (Scheme 2). All structures of the novel intermediates and target compounds were confirmed by ^1H NMR, ^{13}C NMR and HRMS (ESI).

Anti-proliferation activities and summary of SARs

Cytotoxicity of all the synthesized compounds was evaluated against four different human cancer cell lines. The inhibitory activities (IC_{50}) of all of the synthesized compounds were determined (as shown in Table 4). In general, most of the compounds exhibited greater potency on suspension cell lines (HL-60, K562) than toward attached cell lines (HeLa, A549). For example, compound **6a** showed excellent anti-proliferative activity with an IC_{50} value of $0.69 \mu\text{M}$ for the HL-60 cell line, which was equal to the IC_{50} value for the positive control VP-16 and far exceeded the lead compound MsF.

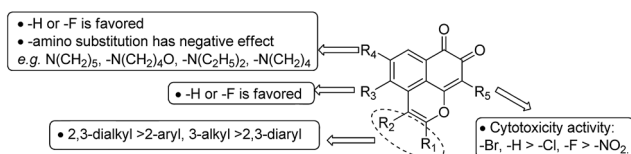

The structure-activity relationships (SARs) showed that the type and position of the substitutions play an important role in determining the anti-proliferative potency (as shown in Fig. 2). First, substitution at the C-9 position was crucial for the cytotoxicity of MsF derivatives. In general, cytotoxicity of the 9-substituted derivatives followed the order $-\text{Br} \approx -\text{H} > -\text{Cl} \approx -\text{F} > -\text{NO}_2$. The 9-Br-substituted derivatives (*e.g.* **6a**, **6c**, **6d**, **6e** and **6f**) showed remarkable growth inhibitory activity against most of the tested

cell lines. Second, substitution at the C-2 and C-3 positions with flexible alkyl chain (e.g., series **a** with 2,3-diEt, series **d** with 2,3-diPr, series **e** with 2,3-diBu, and series **f** with 2,3-diPent) yielded better cytotoxic activity than substitution with a rigid aromatic ring (e.g., series **b** with 2-Ph, 3-Me and series **c** with 2,3-diPh). Alkyl chain length had no influence on cytotoxicity. Finally, compared with the **a** series without 4,5-position substitutions (e.g., **3a–7a**), 4,5-diF substituted derivatives (e.g., **13** and **14**) could maintain cytotoxic activity. However, reduced cytotoxic activity was observed when the 5-fluorine atom of compound **13** was replaced by other amino groups (e.g., series **16**).

Conclusions

In summary, a novel and convenient synthetic route for MsF derivatives was established. The key step for synthesizing MsF derivatives involved the rapid construction of oxaphenylene structure by a one-step reaction of Ru(II)-catalyzed C–H functionalization.

This concise and practical synthetic procedure allows easy induction of a variety of substituents at the C-2, C-3, C-4, C-5 and C-9 positions, and scaled-up production of promising candidate compounds. Furthermore, the cytotoxic activity of synthesized compounds was evaluated in four human cancer cell lines. The SARs of MsF derivatives were discussed in this study and we found that **6a** has excellent anti-proliferative activities which needs to be further studied.

Experimental

General materials and methods

All reactions were monitored by using TLC purchased from Qingdao Haiyang Chemical Co. Ltd. High resolution mass spectra (HRMS) were recorded on Shimadzu LCMS-IT-TOF in electrospray ionization (ESI) positive or negative modes. Melting points (Mp) were determined using a SRS-OptiMelt automated melting point instrument without correction. ¹H (400 MHz), ¹³C NMR (100 MHz), HMBC, HMQC and NOESY were recorded on a Bruker BioSpin GmbH spectrometer with tetramethylsilane (TMS) as an internal standard. IR spectra were recorded on Bruker Equinox 55 Fourier transform spectrometer. The purification of synthesized compounds were carried out by using flash column chromatography with silica gel (200–300 mesh) purchased from Qingdao Haiyang Chemical Co. Ltd. Their purities were proved to be higher than 95% by using analytical HPLC equipped with Shimadzu LC-20AB system and an Ultimate XB-C18 column (4.6 × 250 mm, 5 μm) at a flow rate of 0.25 mL min^{−1}. The detection wavelength was 254 nm, and the mobile phase was methanol–water (80 : 20–60 : 40) containing 0.1% TFA. The main text of the article should appear here with headings as appropriate.

Cell culture and cell lines. The human acute promyelocytic leukemia cell HL-60, human chronic myelogenous leukemia cell K-562, human cervical cancer cell HeLa, human lung cancer cell A549 were obtained from the American Type Culture Collection (ATCC, Rockville, MD) and preserved at our lab. The HL-60 and K-562 cells were cultured in a RPMI-1640 medium (Gibco, Carlsbad, CA) supplemented with 10% fetal bovine serum (Gibco, Carlsbad, CA), and other cell lines were grown in Dulbecco's Modified Eagle's Medium (D-MEM, Gibco Carlsbad, CA) supplemented with 10% fetal bovine serum. All cells were cultured with 5% CO₂ at 37 °C.

Synthetic procedures

General procedure for synthesis of 2a–2f. A suspension of 4-nitronaphthalen-1-ol (945.0 mg, 5.00 mmol), alkyne (5 mmol), [RuCl₂(*p*-cymene)]₂ (48 mg, 1.5% mmol) and Cu(OAc)₂·H₂O (955 mg, 5 mmol), and dimethylformamide (8.0 mL) in

ChemGlass pressure vessel was stirred at 100 °C for 9–16 h. After the starting material was consumed up, the reaction mixture was cooled to room temperature, diluted with dichloromethane, and filtered with a short column chromatography on silica gel. The organic layers were washed with water (3 × 30 mL) and dried over Na₂SO₄. After filtration, the filtrate was collected and the solvent was removed under reduced pressure, the crude product was purified by using column chromatography on silica gel (petroleum ether) to give the target compounds.

General procedure for synthesis of 3a–3f. Sodium hyp-sulfite (1.74 g, 10 mmol, 5 equiv.) was added to a solution of nitro-substituted products (2a–2f, 2 mmol) in THF/H₂O (120 mL, 3 : 1). The reaction mixture was heated to 50 °C and further stirred for 2 h at this temperature. After the starting material was consumed up, the reaction mixture was concentrated to remove the THF under reduced pressure and then the residue was extracted with dichloromethane (30 mL × 3). The combined extracts were evaporated to remove the solvent. The solid residue was dissolved in acetone (60 mL) and a solution of Fremy's salt (1.34 g, 5 mmol, 2.5 equiv.) in 0.06 M KH₂PO₄ solution (68 mL) was added with vigorous stirring. After stirring for 1 h, the mixture was extracted with dichloromethane (30 mL × 3). The combined extracts were washed with brine (30 mL), dried over Na₂SO₄, filtered and evaporated to dryness. The solid residue was purified by using flash column chromatography (silica gel), eluting with 5% ethyl acetate in dichloromethane to give the target compounds.

2,3-Diethylbenzo[de]chromene-7,8-dione (3a). Reddish brown solid, yield 65%. General procedure for synthesis of 7a–7f. O-Quinone product (3a–3f, 0.5 mmol) was dissolved in acetic anhydride (25 mL) and cooled to 0 °C in an ice bath. Cupric nitrate (0.6 mmol, 1.2 equiv.) was added under stirring. The reaction mixture was warmed up to room temperature, and stirring was continued until the reaction was completed. The mixture was slowly poured into chopped ice, and the resulting mixture was extracted with DCM. The combined organic layer was washed with water (3 times) and concentrated to give a crude product under reduced pressure. The crude product was purified by

using column chromatography (silica gel), eluting with dichloromethane to give the target compound.

6,7-Difluoro-1,4-dihydro-1,4-epoxynaphthalene (9). A 500 mL, 3-neck, round-bottom flask, which was equipped with a condenser, rubber seal, gas adapter under N_2 , was charged 50 mL of THF, 150 mmol furan and 1.44 g of Mg (60 mmol, 1.2 equiv.). The solution which was heated to 75 °C, was added **8** (10.55 g, 50 mmol) in 30 mL of THF *via* gastight syringe over a 1 h period at such a rate to keep the reaction mixture. The reaction mixture was then stirred for 8 h at 75 °C. Then 20 mL of water was poured into the reaction mixture to halt the reaction, and the aqueous phase was washed (3 × 50 mL) with ether. The combined organic phases were dried over Na_2SO_4 , vacuum filtered, and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (petroleum ether/EtOAc = 20 : 1, 10 : 1, 8 : 1, 5 : 1) to afford **9** (4.89 g, 31%) as yellow oily liquid. ^1H NMR (400 MHz, CDCl_3) δ 7.07 (t, J = 7.7 Hz, 2H), 7.03 (t, J = 1 Hz, 2H), 5.69 (s, 2H). ^{13}C NMR (101 MHz, CDCl_3) δ 148.5 (d, J = 14.9), 146.0 (d, J = 14.9), 145.2 (t, J = 4.6 Hz), 143.1, 110.9 (m), 82.1.

6,7-Difluoronaphthalen-1-ol (10). To a stirred solution of **9** (5.76 g, 1.5 mmol) in CH_2Cl_2 (30 mL), diluted $\text{BF}_3 \cdot \text{Et}_2\text{O}$ (4.84 mL) was added slowly and stirred for 1 h at 0 °C. After the starting material was consumed up, the solution was washed with water (40 mL) and dried over Na_2SO_4 , and then the solvent was removed under reduced pressure. The residue was purified by silica gel column chromatography (petroleum ether/EtOAc = 10 : 1) to afford **10** (4.89 g, 84.9%) as white solid. ^1H NMR (400 MHz, CDCl_3) δ 7.94 (t, J = 9.5 Hz, 1H), 7.52 (t, J = 9.0 Hz, 1H), 7.35 (d, J = 8.4 Hz, 1H), 7.32–7.27 (m, 2H), 6.80 (d, J = 7.1 Hz, 1H), 5.36 (bs, 1H). ^{13}C NMR (101 MHz, CDCl_3) δ 150.9 (d, J = 5.1 Hz), 150.5 (dd, J = 249.6, 14.7 Hz), 149.6 (dd, J = 248.5, 15.2 Hz), 131.8 (d, J = 7.7 Hz), 126.4 (d, J = 2.3 Hz), 121.1 (d, J = 6.8 Hz), 119.9 (dd, J = 4.7, 1.6 Hz), 113.3 (d, J = 16.77 Hz), 108.7 (d, J = 5.8 Hz), 106.6 (d, J = 10.3 Hz).

2,3-Diethyl-4,5-difluorobenzo[de]chromene (11). A suspension of **10** (900 mg, 5.00 mmol), 3-hexyne (5 mmol), $[\text{RuCl}_2(p\text{-cymene})]_2$ (48 mg, 1.5% mmol) and $\text{Cu}(\text{OAc})_2 \cdot \text{H}_2\text{O}$ (955 mg, 5 mmol), and *m*-xylene (8.0 mL) in ChemGlass pressure vessel was stirred at 80–100 °C overnight. After the starting material was consumed up, the reaction mixture was cooled to room temperature, diluted with dichloromethane, and filtered with a short column chromatography on silica gel. The organic layers were washed with water (3 × 30 mL) and dried over Na_2SO_4 . After filtration, the filtrate was collected and the solvent was removed under reduced pressure, the crude product was purified by using column chromatography on silica gel (petroleum ether) to give **11** (54%) as pale yellow oily liquid. ^1H NMR (400 MHz, CDCl_3) δ 7.24 (t, J = 8.0 Hz, 1H), 7.10 (dd, J = 8.1, 0.6 Hz, 1H), 7.03 (dd, J = 11.1, 7.2 Hz, 1H), 6.71 (d, J = 7.7 Hz, 1H), 2.59 (qd, J = 7.4, 2.2 Hz, 2H), 2.46 (q, J = 7.5 Hz, 2H), 1.26 (t, J = 7.2 Hz, 3H), 1.20 (td, J = 7.4, 1.0 Hz, 3H). ^{13}C NMR (101 MHz, CDCl_3) δ 154.7 (d, J = 2.2 Hz), 152.3 (dd, J = 248.2, 17.4 Hz), 152.1 (dd, J = 4.7, 1.9 Hz), 140.8 (dd, J = 247.3, 17.5 Hz), 131.57 (d, J = 5.5 Hz), 129.0, 127.4 (d, J = 1.6 Hz), 126.3, 120.2 (d, J = 5.1 Hz), 118.4 (dd, J = 5.0, 1.7 Hz), 110.0 (dd, J = 5.4, 3.2 Hz), 107.8

2,3-Diethyl-4,5-difluorobenzo[de]chromene-7,8-dione (13). Sodium hyposulfite (1.74 g, 10 mmol, 5 equiv.) was added to a solution of **12** (2 mmol) in THF/ H_2O (120 mL, 3 : 1). The reaction mixture was heated to 50 °C, and further stirred for 2 h at this temperature. After the starting material was consumed up, the reaction mixture was concentrated to remove the THF under reduced pressure and then the residue was extracted with dichloromethane (30 mL × 3). The combined extracts were evaporated to remove the solvent. The solid residue was then dissolved in acetone (60 mL) and a solution of Fremy's salt (1.34 g, 5 mmol, 2.5 equiv.) in 0.06 M KH_2PO_4 solution (68 mL) was added with vigorous stirring. After stirring for 1 h, the mixture was extracted with dichloromethane (30 mL × 3). The combined extracts were washed with brine (30 mL), dried over Na_2SO_4 , filtered and evaporated to dryness. The solid residue was purified by using flash column chromatography (silica gel), eluting with 5% ethyl acetate in dichloromethane to give **13** (45.19%) as purple black solid. Mp: 145.2–148.5 °C. General procedure for synthesis of compounds 16. A solution of K_2CO_3 (552 mg, 4 mmol), **12** (2 mmol), different amine (6 mmol) in DMF (20 mL) was stirred in 60 °C for 12 h. Then H_2O (40 mL) was added and extracted with CH_2Cl_2 (3×30 mL). The combined organic phases were dried over Na_2SO_4 , and the solvent was removed under reduced pressure to get the crude product. The next step was similar to the synthesis of **13**.

2,3-Diethyl-4-fluoro-5-(piperidin-1-yl)benzo[de]chromene-7,8-dione (16a). **16a** was prepared from K_2CO_3 (552 mg, 4 mmol), **12** (2 mmol), piperidin (6 mmol), purple black solid, yield 65%. Mp: 167.9–169.4 °C. IR ν_{\max} (KBr) cm^{-1} : 1630, 1696. ^1H NMR (400 MHz, CDCl_3) δ 7.76 (t, J = 5.4 Hz, 1H), 5.94 (d, J = 6.1 Hz, 1H), 3.20 (d, J = 4.2 Hz, 4H), 2.70 (s, 2H), 2.64–2.58 (m, 2H), 1.75 (s, 4H), 1.65 (s, 2H), 1.29–1.24 (m, 3H), 1.20 (d, J = 6.8 Hz, 3H). ^{13}C NMR (101 MHz, CDCl_3) δ 179.9, 177.9, 165.7, 155.5, 153.4 (d, J = 262.9 Hz), 145.4 (d, J = 10.1 Hz), 126.6 (d, J = 3.9 Hz), 122.6 (d, J = 6.0 Hz), 121.3 (d, J = 12 Hz), 115.5 (d, J = 5.7 Hz), 111.4 (d, J = 4.3 Hz), 102.4, 51.6 (d, J = 4.4 Hz), 25.9, 24.0, 23.9, 21.6 (d, J = 12.1 Hz), 15.1 (d, J = 4.4 Hz), 12.5. MTT assay

Four different cancer cell lines, including HeLa, A549, K562 and HL-60 were used to evaluate the growth inhibitory effect of MsF derivatives by using the MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-2H-tetrazolium-bromide) assay as described by Mosmann with modifications.²³ The cells were plated at a density of 1×10^4 per well in 96-well microplates, and allowed to incubate overnight in a 5% CO_2 incubator at 37 °C. MsF derivatives were added to the wells at increasing concentrations (0–50 μM). After 48 h, each well was treated with 20 mL 2.5 mg mL^{-1} MTT solution, and the cells were further incubated at 37 °C for 4 h. At the end of the incubation, the untransformed MTT was removed, and 100 μL of DMSO was added for HeLa and A549 cell lines. K562, and HL-60 cell lines were treated with three linked lysis solution, and then incubated at 37 °C overnight. The microplates were well shaken to dissolve the formazan dye, and the absorbance at 570 nm was measured using a microplate-reader (Bio-Tek). VP-16 were commercially available and used as positive controls.
