## Development of a compact MnO<sub>2</sub> filter for removal of SO<sub>2</sub> from diesel vehicle emissions

Xuecheng Liu,<sup>ab</sup> Yugo Osaka,<sup>c</sup> Hongyu Huang,<sup>id</sup>\*<sup>a</sup> Jun Li,<sup>\*d</sup> Zhaohong He,<sup>a</sup> Xixian Yang,<sup>a</sup> Huhetaoli,<sup>a</sup> Shijie Li<sup>a</sup> and Noriyuki Kobayashi<sup>d</sup>

Increasing concern about sulfur dioxide (SO<sub>2</sub>) from diesel vehicle exhausts causing detrimental effects on NO<sub>x</sub> removal catalysts has resulted in the development of dry desulfurization filters for complete removal of SO<sub>2</sub>. In this study, a compact MnO<sub>2</sub> filter was developed for diesel emission control. The SO<sub>2</sub>-capture behavior of the compact MnO<sub>2</sub> filter was investigated by using a volumetric device in a low temperature range (200–400 °C) and low SO<sub>2</sub> pressure conditions. The maximal capacity of the MnO<sub>2</sub> filter was 304.1 mg<sub>SO<sub>2</sub></sub> per g<sub>MnO<sub>2</sub></sub> at 400 °C. Based on the experimental results, the required volume of the MnO<sub>2</sub> filter was estimated as only 0.6 L for a diesel car with 30 000 km distance traveled per year. The thickness of the MnO<sub>2</sub> filter had significant influence on its SO<sub>2</sub>-capture performance. The sulfate reaction mechanism was also discussed by using a grain model under four reaction temperature conditions for improving the efficiency of the design of the desulfurization filter. The sulfate process can be divided into two control stages (the chemical reaction control stage and the solid diffusion control stage) and the prediction models fit the experimental data well for both control stages, indicating that the two-stage grain model is suitable for the sulfate reaction between the MnO<sub>2</sub> filter and SO<sub>2</sub>. The calculated apparent activation energy of 18.8 kJ mol<sup>-1</sup> indicates that the MnO<sub>2</sub> filter exhibits high activity for SO<sub>2</sub> adsorption in a pure SO<sub>2</sub> atmosphere.

## Introduction

The removal of sulfur dioxide (SO<sub>2</sub>) from vehicle exhausts is of great interest for the reason that SO<sub>2</sub> has detrimental effects on human health and the environment.<sup>1,2</sup> Besides, SO<sub>2</sub> from diesel vehicle exhaust gas greatly deactivates the NO<sub>x</sub> removal catalysts because sulfates are more stable than nitrates.<sup>3</sup> Compared with the flue gas from large power plants, diesel exhaust gas is quite different because of the low emission amounts, wide temperature range, high space velocity and low sulfur concentration (the sulfur content of diesel varying from tens of ppm to hundreds of ppm). Therefore the traditional wet flue gas desulfurization technologies for large power plants are not suitable for diesel exhaust systems. To solve the issues caused by SO<sub>2</sub> emissions from diesel exhausts, compact SO<sub>2</sub> traps of dry desulfurization technologies have been proposed for complete capture of SO<sub>2</sub> from diesel vehicle exhausts.<sup>4–7</sup>

The traditional dry desulfurization materials, such as calcined limestone<sup>8</sup> and CaCO<sub>3</sub> materials,<sup>9</sup> have good sulfate reactivity over 650 °C with high SO<sub>2</sub> concentration over 1000 ppm. However, SO<sub>2</sub> capture capacity of these materials declines sharply below 400 °C because the sulfate reaction activity is limited by the decarbonation.<sup>9</sup> With continuous development of the diesel engine technology, the maximum temperature of diesel exhaust will be decreased to 400 °C. Therefore the development of low-temperature activation and downsizing of the compact SO<sub>2</sub> trap is needed for mounting on mobile diesel vehicle.

To enhance the low-temperature SO<sub>2</sub>-capture performance of desulfurization materials, Rubio and Izquierdo<sup>10</sup> studied the SO<sub>2</sub> removal performance of coal fly ash based carbons at flue gas conditions and the amount of SO<sub>2</sub> removed is 13 mg g<sup>-1</sup> by the Lada activated sample at 100 °C and 1000 ppmv SO<sub>2</sub> gas conditions. The SO<sub>2</sub> oxidation activity of copper oxide supported on the activated carbon could be improved at low temperature at 250 °C.<sup>11,12</sup> The SO<sub>2</sub> capture capacity of CeO<sub>2</sub> based materials was investigated at low temperature conditions.<sup>13–15</sup> Manganese dioxide with a simple sulfate reaction path (MnO<sub>2</sub> + SO<sub>2</sub> → MnSO<sub>4</sub>) showed high SO<sub>2</sub>-capture capacity at low temperature conditions.<sup>16</sup> The MnO<sub>2</sub> with high specific surface area had the potential to be more compact for disposable SO<sub>2</sub> traps on account of high desulfurization SO<sub>2</sub>-capture performance at low temperature conditions. Li *et al.*<sup>17</sup> investigated the SO<sub>2</sub> capture capacity of manganese oxide at 325 °C

and found that cryptomelane could be application as a replaceable adsorbent for the removal of SO<sub>2</sub> from diesel exhaust.

Traditionally, the materials were wash-coated on ceramic carrier (Fig. 1a) by using the binder for final application in the diesel vehicle exhaust system.<sup>18–20</sup> The SO<sub>2</sub> capture capacity per unit volume of desulfurization filter greatly decreased because the ceramic carrier with low SO<sub>2</sub>-capture performance occupied too much volume of the filter. Moreover, as the sulfur concentration of diesel is very small (a few hundred ppm), the mutual diffusion resistance could be large, which will greatly lower the diffusion rate of SO<sub>2</sub> reaction gas from the external air to the sites of the reactant.<sup>21</sup> Therefore, in this study, the compact dry desulfurization filter without ceramic carrier (MnO<sub>2</sub> filter) was developed to downsize the desulfurization filter, as shown in Fig. 1b, and the volumetric method was proposed to exclude the mutual diffusion resistance to obtain the real SO<sub>2</sub>-capture behavior of compact MnO<sub>2</sub> filter. The effects of the reaction temperature and thickness of MnO<sub>2</sub> filter were investigated at low SO<sub>2</sub> pressure condition. The sulfate reaction mechanism between the MnO<sub>2</sub> filter and pure SO<sub>2</sub> was also discussed under four reaction temperature conditions for improving the efficiency of designing MnO<sub>2</sub> filter.

## Experimental

### MnO<sub>2</sub> filter preparation

50 mg MnO<sub>2</sub> was blended with 5 mg Carboxymethyl Cellulose (CMC) in the beaker. Exactly 2 mL of silica-sol (3.4 w% in H<sub>2</sub>O) was added dropwise and mixed the blender by glass rod. Then, the blender was extruded through the metal mold and calcined at 400 °C to form a rounded compact MnO<sub>2</sub> filter. The MnO<sub>2</sub> used for experiments was supplied by Japan Material and Chemical Co., Ltd. These materials were obtained by the acid treatment of raw material. The chemicals, CMC and silica sol (34 w% suspension in H<sub>2</sub>O), were purchased from Aladdin Co., Ltd., People's Republic of China and were of analytical reagent grade.

### Characterization

Morphology of the sample was analyzed by using transmission electron microscope (TEM). In this study, specific surface area, average pore diameter and pore volume were conducted to assess the physical characteristics of the target sample. The specific surface area was measured by the Brunauer–Emmett–Teller with the nitrogen adsorption uptake at the boiling point

of nitrogen of 77 K using a capacitive measurement method. The average pore diameter and pore volume were measured by nitrogen physisorption under normal relative pressure of 0.1–1.0 using the Barrett–Joyner–Halenda (BJH) method. The particle size distribution of the sample was analyzed by Malvern laser particle size analyzer.

### Volumetric measurements

The volumetric test-rig consists mainly of two compartments, as depicted in Fig. 2. The first is sample cell, in which a sample of 0.1 g rounded adsorbent is placed. The reaction temperature of sample cell can be adjusted and controlled by using the heater cover. The second compartment is a large constant volume tank. The temperature of this tank is controlled by using a thermostatic chamber.

The volumetric test-rig was used in this study to measure the SO<sub>2</sub> capture capacity of the prepared adsorbent. Table 1 presents the experimental conditions used in the present study. The MnO<sub>2</sub> filter was placed into the sample cell and slowly heated (5 K min<sup>-1</sup>) to the target reaction temperature. At the same time, the tank and sample was evacuated for 1 h by using the vacuum 1 with the valves V1–V3 opened. After the pressure was below 10<sup>-2</sup> Pa, the valves V1–V3 were closed. The valves V4 & V2 were slowly opened to put the SO<sub>2</sub> gas into the tank and then closed when the pressure of the SO<sub>2</sub> gas was up to 40 Pa (equivalent to the partial pressure of 400 ppm SO<sub>2</sub> in the exhaust). The temperature of thermostatic chamber was kept at 35 °C. The sulfate reaction process started once the valve V1 was opened, leading to decreasing the pressure in the tank. The pressure

Fig. 2 Schematic diagram of the volumetric test-rig.

Table 1 Experimental conditions

| Variables                                   | Conditions |
|---|------------|
| Temperature of the thermostatic chamber (K) | 308        |
| Temperature of the sample (K)               | 473–673    |
| Pressure of tank (Pa)                       | 40         |
| Mass of the sample (g)                      | 0.05–0.15  |
| Thickness of the adsorbent sample (mm)      | 0.5–2      |

variation was measured to determine the amount of the SO<sub>2</sub> gas on the sorbent sample by using the high resolution ceramic capacitance manometer P2. The SO<sub>2</sub> capture capacity per unit mass of absorbent  $C$  and the conversion of MnO<sub>2</sub>  $X$  are expressed by the following equations:

$$C = \frac{(P_0 - P_t)V}{RT} \frac{M_{\text{SO}_2}}{s_0} \quad [\text{g}_{\text{SO}_2} \text{ per } \text{g}_{\text{material}}] \quad (1)$$

$$X = \frac{M_{\text{MnO}_2}}{M_{\text{SO}_2}} \frac{C}{\omega s_0} \quad [\text{g}_{\text{SO}_2} \text{ per } \text{g}_{\text{MnO}_2}] \quad (2)$$

$C$  is the SO<sub>2</sub> capture performance per unit mass [g<sub>SO<sub>2</sub></sub> per g<sub>material</sub>],  $R$  is the ideal gas constant,  $V$  is the volume of the SO<sub>2</sub> gas,  $P_0$  is the initial pressure of the absorbent [Pa],  $P_t$  is the pressure after  $t$  seconds [Pa],  $s_0$  is the initial weight of the absorbent [mg];  $X$  is the conversion of MnO<sub>2</sub>,  $\omega$  is the mass fraction of MnO<sub>2</sub> in the absorbent,  $M_{\text{MnO}_2}$  is the molar mass of MnO<sub>2</sub> [g mol<sup>-1</sup>],  $M_{\text{SO}_2}$  is the molar mass of SO<sub>2</sub> [g mol<sup>-1</sup>].

## Results and discussion

### Material characterization

The distribution of pore diameter of the prepared sample is displayed in Fig. 3. From the results of Fig. 3, the relatively large pore diameter of the sample is about 7 nm. The specific surface area, average pore diameter and pore volume of the prepared sample are 275 m<sup>2</sup> g<sup>-1</sup>, 7.5 nm and 0.5 cm<sup>3</sup> g<sup>-1</sup>, respectively. The relatively large particle diameter of the sample is about 1.6 μm. XRD analysis (Fig. 4) is carried out to study the crystal structure of MnO<sub>2</sub> filter before and after desulfurization. From the results of Fig. 4, the diffraction peaks of MnO<sub>2</sub> filter are similar to those of tetragonal phase MnO<sub>2</sub> (JCPDS 00-044-0141), and after desulfurization the diffraction peaks of the sample are changed to the orthorhombic phase MnSO<sub>4</sub> (JCPDS 00-011-0088).

### Basic SO<sub>2</sub>-capture performance of MnO<sub>2</sub> filter by using volumetric device

Fig. 5 shows the effect of desulfurization temperature on SO<sub>2</sub> capture capacity of MnO<sub>2</sub> filter. The SO<sub>2</sub> capture capacity of

Fig. 3 Distribution of pore diameter of the prepared sample.

Fig. 4 XRD patterns of MnO<sub>2</sub> filter (a) before and (b) after desulfurization.

MnO<sub>2</sub> filter was investigated at 200 °C, 300 °C, 350 °C and 400 °C. From the results shown in Fig. 5, the SO<sub>2</sub> capture capacity of MnO<sub>2</sub> filter increases with the experimental temperature. At these experimental conditions, the trap achieves the highest SO<sub>2</sub> capture capacity and obtained about 76.3 mg<sub>SO<sub>2</sub></sub> per g<sub>MnO<sub>2</sub></sub> after 1 h at 400 °C. At 200 °C, the SO<sub>2</sub> trap capacity decreased to about 20% of its capacity at 400 °C and

Fig. 5 Influence of temperature on SO<sub>2</sub> capture performance of MnO<sub>2</sub> filter at 200 °C, 300 °C, 350 °C and 400 °C.

Table 2 SO<sub>2</sub> capture capacity (mg<sub>SO<sub>2</sub></sub> per g<sub>MnO<sub>2</sub></sub>) of MnO<sub>2</sub> filter at 200–400 °C, 40 Pa pure SO<sub>2</sub>

| Reaction temperature | 200 °C | 300 °C | 350 °C | 400 °C |
|----------------------|--------|--------|--------|--------|
| After adsorption 1 h | 15.0   | 25.7   | 52.7   | 76.3   |
| Maximal capacity     | 15.0   | 25.7   | 71.7   | 304.1  |

obtained 15.0 mg<sub>SO<sub>2</sub></sub> per g<sub>MnO<sub>2</sub></sub>. SO<sub>2</sub> capture capacity (mg<sub>SO<sub>2</sub></sub> per g<sub>MnO<sub>2</sub></sub>) of MnO<sub>2</sub> filter at 40 Pa pure SO<sub>2</sub> under different sulfate reaction temperature conditions has been listed in Table 2. As seen in the results of Table 2, the maximal capacity of MnO<sub>2</sub> filter was 304.1 mg<sub>SO<sub>2</sub></sub> per g<sub>MnO<sub>2</sub></sub> at 400 °C, significantly higher than the traditional desulfurization materials,<sup>14,17,22</sup> as shown in Table 3.

Based on the experimental results, the optimum volume of the MnO<sub>2</sub> filter required for a diesel engine was estimated. A diesel car (traveled distance: about 30 000 km of one year) is considered in which the concentrations of sulfur in the diesel oil and in lubricating oil are both 30 ppm. It is assumed that the SO<sub>2</sub>-capture capacity is not affected by the initial sulfur concentration in this evaluation. Fuel consumption of the diesel car is 7 liter per hundred kilometers. The specific gravity of diesel oil is 0.83 kg L<sup>-1</sup>. The amount of discharged SO<sub>2</sub> for one year is 104.6 g. Based on the evaluation that the SO<sub>2</sub> capture capacity at a reaction temperature of 400 °C is 182.5 g<sub>SO<sub>2</sub></sub> per L<sub>MnO<sub>2</sub> filter</sub> (SO<sub>2</sub> capture performance is 304.1 mg<sub>SO<sub>2</sub></sub> per g<sub>MnO<sub>2</sub></sub> at 400 °C and the density of MnO<sub>2</sub> filter is 0.6 g cm<sup>-3</sup>), this means that a 1.0 L MnO<sub>2</sub> filter can capture 182.5 g of SO<sub>2</sub>. Therefore, the required volume of the MnO<sub>2</sub> filter was calculated as only 0.6 L for a diesel vehicle with 30 000 km traveled distance per one year, remarkably smaller than the traditional wash-coated desulfurization filter.<sup>7</sup> Moreover, as a part of the storage sites on MnO<sub>2</sub> after regeneration are non-renewable<sup>16</sup> and the desulfurization product (MnSO<sub>4</sub>) is always in great demand for the industrial and agricultural raw material, MnO<sub>2</sub> filter could be suitable for the disposable desulfurization filter without being recycled every year for economy.<sup>23</sup>

### The effect on SO<sub>2</sub> capture capacity of MnO<sub>2</sub> filter with different thickness

In the traditional SO<sub>2</sub> traps,<sup>4</sup> the amount of SO<sub>2</sub> capture was dependent on the quantity of sorbents in the desulfurization trap. In this study, similar experimental results were obtained. The amount of SO<sub>2</sub> adsorption was proportional to the thickness of MnO<sub>2</sub> filter, as shown in Fig. 6. The thickness of

Fig. 6 Effect of the thickness of the MnO<sub>2</sub> filter on the amount of SO<sub>2</sub> adsorption.

materials had much influence on the removal performance of diesel exhaust purifier.<sup>24</sup> The dimensionless SO<sub>2</sub> capture performance per unit mass (mg<sub>SO<sub>2</sub></sub> per g<sub>MnO<sub>2</sub></sub>)-time (*t*) curve of MnO<sub>2</sub> filter with different thickness was obtained by using the volumetric test-rig. As shown in Fig. 7, the shape of the curve is different when the packing height is changed. The SO<sub>2</sub> capture rate of MnO<sub>2</sub> filter decreased with the thickness. The 0.5 mm-thick MnO<sub>2</sub> filter showed the highest SO<sub>2</sub> capture rate than 2 mm-thick MnO<sub>2</sub> filter. The reason is that the mass transfer resistance of gas diffusion in the thicker layer is larger than that in the thinner layer in the adsorbent.<sup>7</sup>

### Sulfate reaction mechanism

The sulfate reaction mechanism is very important for improving the efficiency of designing the desulfurization filter. In this study, in order to investigate the sulfate reaction mechanism between MnO<sub>2</sub> filter and sulfur dioxide, the MnO<sub>2</sub> filter with thin layer and low density was prepared to minimize the gas

Fig. 8 Effect of temperature on solid conversion of MnO<sub>2</sub> filter at 40 Pa of SO<sub>2</sub> gas pressure.

diffusion resistance in the traps. Moreover, a series of experiments were carried out at four reaction temperature conditions (200 °C, 300 °C, 350 °C and 400 °C) with low SO<sub>2</sub> pressure of 40 Pa. Fig. 8 shows the conversion-time profiles of MnO<sub>2</sub> filter for different temperature at low SO<sub>2</sub> pressure of 40 Pa. As this figure shows, the reaction rate increases considerably at higher temperatures. The sulfate degree in the experimental conditions increased steeply at the beginning of the reaction, and then the slopes of sulfate degree curves become gradual after ~5 min.

The sulfate reaction between manganese dioxide and sulfur dioxide with a simple reaction path ( $\text{MnO}_2 + \text{SO}_2 \rightarrow \text{MnSO}_4$ ) is a solid-gas non-catalytic reaction. Various models had been discussed to describe the mechanism of the solid-gas non-

catalytic reaction.<sup>25</sup> Among these models, the grain model was a suitable mathematical representation of gas-solid reactions in chemical and metallurgical industries consist of solid pellets produced from small particles or grains, which assumes that the reaction was accomplished on the surface of the fine and non-porous grains.<sup>26</sup> TEM were employed to obtain surface features of the samples before and after desulfurization, the results as shown in the Fig. 9. Based on the TEM images in Fig. 9, the prepared MnO<sub>2</sub> filter was formed with a series of smooth spherical grains and these grains are non-porous. Therefore, the grain model should be suitable for the solid-gas reaction between MnO<sub>2</sub> filter and SO<sub>2</sub>.

In the grain model, the sulfate rate is controlled by four steps: external diffusion, gas reactant diffusion to the external surfaces of the solid particles from the bulk gas phase; surface reaction, gas reactant being adsorbed on the solid reactant surface; solid diffusion, gas reactant diffusion through the product layers; internal diffusion, gas reactant intra-particle transport through pores. For the whole systems, the controlling regime changes with the reaction time and was continuously consumed because the solid is a reactant.<sup>27</sup> Most solid-gas non-catalytic reactions always presented two consecutive stages: the initial stage with the fast sulfate rate was controlled by the surface chemical reaction; the second stage with the slower sulfate rate was controlled by the product layer diffusion.<sup>28,29</sup> According to the grain model, the relationship between the solid conversion equation  $X$  and the reaction time  $t$  at the chemical reaction control stage for the spherical particle and grain can be expressed by the following equation:

$$t = \frac{\rho_s r_g}{bk_s C_A} \left[ 1 - (1 - X)^{1/3} \right] \quad (3)$$

Fig. 9 TEM images of MnO<sub>2</sub> filter before (a, b) and after desulfurization (c, d).

where  $\rho_s$  is the solid reactant concentration,  $k_s$  is the surface chemical reaction rate constant,  $C_A$  is the concentration of reactant gas,  $b$  is the stoichiometric coefficient of the reaction,  $r_g$  is the initial radius of the spherical grain,  $X$  the conversion of solid reactant. The relationship between the solid conversion equation  $X$  and the reaction time  $t$  at the solid diffusion control stage for the spherical particle and grain can be expressed by the following equation:

$$t = \frac{\rho_s r_g^2}{6bkD_e C_A} \left[ t_0 + 1 - 3(1-X)^{2/3} - 2(1-X) \right] \quad (4)$$

where  $D_e$  is the effective diffusivity,  $t_0$  is the revision factor of the delay time for sulfate rate from the chemical reaction control stage to solid diffusion control stage.

The grain model prediction of chemical reaction control, expressed in eqn (3), was applied to curve-fitting for the beginning of the sulfate process (the initial stage); and the grain model prediction of solid diffusion control, expressed in eqn (4), was applied to fit experimental data for the increase reaction time of sulfate process (the second stage). Fig. 10 shows the lines of the model predictions of chemical reaction control and solid diffusion control under the different reaction temperature conditions. From the results shown in Fig. 10, it can be seen that the prediction models fit the experimental data well for both control stages at 200 °C and 300 °C. At 350 °C and 400 °C, the prediction model of chemical reaction control fit the experimental data well at the initial stage of sulfate process. At higher temperature, the sulfate rate was controlled the zone of sulfate reaction between porous solid and gas became a relative narrow with the sulfate reaction proceeding and the surface reaction rate and diffusion rate were of the same order of magnitude.<sup>30</sup> Therefore, the sulfate rate could be controlled by the chemical reaction and solid diffusion at the second stage at 350 °C and 400 °C. Generally, it can be safely concluded that the grain model is suitable for the solid–gas reaction between MnO<sub>2</sub> filter and SO<sub>2</sub> and the sulfate process could be divided into two control stages (the chemical reaction control stage and the solid diffusion control stage) under the experimental conditions.

Fig. 10 Experimental data and model predictions of MnO<sub>2</sub> conversion under four reaction temperature conditions.

Fig. 11 Arrhenius plot of sulfate rate of MnO<sub>2</sub> filter with chemical reaction control.

In order to determine the activation energy of the sulfate reaction between the MnO<sub>2</sub> filter and pure SO<sub>2</sub>, the sulfate reaction rate constant of the chemical reaction control stage was measured at 200 °C, 300 °C, 350 °C and 400 °C. The corresponding Arrhenius plot is shown in Fig. 11. The apparent activation energy of 18.8 kJ mol<sup>-1</sup> was calculated by using Arrhenius equation under the experimental conditions. Compared with the value of sulfate reaction of manganese oxide (33.5 kJ mol<sup>-1</sup>) reported by Tikhomirov,<sup>31</sup> it can be concluded that in the pure SO<sub>2</sub> atmosphere the MnO<sub>2</sub> filter exhibits high activity for SO<sub>2</sub> adsorption.

## Conclusions

MnO<sub>2</sub> filter is used for compact SO<sub>2</sub> trap to protect the NO<sub>x</sub> removal catalyst against SO<sub>2</sub> poisoning in diesel exhaust system. The SO<sub>2</sub>-capture performance of MnO<sub>2</sub> filter without mutual diffusion resistance was measured by volumetric method under low temperature and low SO<sub>2</sub> pressure conditions. MnO<sub>2</sub> filters with different thickness and packing density were prepared, and the influences of reaction temperature, thickness of MnO<sub>2</sub> filter and recycling characteristic of MnO<sub>2</sub> filter on SO<sub>2</sub> capture capacity were investigated under low temperature range from 200 °C to 400 °C and low SO<sub>2</sub> pressure of 40 Pa conditions. The results of the present work clearly reveal that:

- The maximal capacity of MnO<sub>2</sub> filter was 304.1 mg<sub>SO<sub>2</sub></sub> per g<sub>MnO<sub>2</sub></sub> at 400 °C. The required volume of the MnO<sub>2</sub> filter was estimated as only 0.6 L for a diesel car with 30 000 km traveled distance per one year and MnO<sub>2</sub> filter could be suitable for the disposable desulfurization filter.

- The 0.5 mm-thick MnO<sub>2</sub> filter showed the higher SO<sub>2</sub> capture rate than 2 mm-thick MnO<sub>2</sub> traps because the mass transfer resistance in the thicker layer was larger than that in the thinner layer.

- The grain model is suitable for the sulfate reaction, and the sulfate process can be divided into two control stages (the chemical reaction control stage and the solid diffusion control stage). The prediction models fit the experimental data well for

both control stages. The apparent activation energy of  $18.8 \text{ kJ mol}^{-1}$  was calculated by using Arrhenius equation under the experimental conditions, which exhibits high sulfate activity between the  $\text{MnO}_2$  filter and pure  $\text{SO}_2$ .
