# Effect of an external electric field on the electronic properties of SnS<sub>2</sub>/PbI<sub>2</sub> van der Waals heterostructures

Yaqiang Ma,<sup>a</sup> Xu Zhao,<sup>a</sup> Mengmeng Niu,<sup>a</sup> Xianqi Dai,<sup>\*ab</sup> Wei Li,<sup>a</sup> Yi Li,<sup>a</sup> Mingyu Zhao,<sup>a</sup> Tianxing Wang<sup>a</sup> and Yanan Tang<sup>b</sup>

The future development of optoelectronic devices will require an advanced control technology in electronic properties, for example by an external electric field ( $E_{\text{field}}$ ). Here we demonstrate an approach that the heterostructure based on van der Waals (vdW) heterobilayer built by monolayer SnS<sub>2</sub> and PbI<sub>2</sub> has a well-controlled electronic properties with  $E_{\text{field}}$ . A type-II staggered-gap band alignment is achieved from the SnS<sub>2</sub>/PbI<sub>2</sub> vdW heterostructure with which SnS<sub>2</sub> dominated the lowest energy holes as well as the lowest energy electrons are separated in PbI<sub>2</sub>. The charge redistribution with an  $E_{\text{field}}$  is mainly on the surface of SnS<sub>2</sub> layer and PbI<sub>2</sub> and the numbers of polarized electrons on the monolayers display a linear evaluation with external  $E_{\text{field}}$ . The band structure under different  $E_{\text{field}}$  experiences not only a transition from semiconductor to metal but also conversions between type-I straddling-band alignment and type-II staggered-gap, which results in different spatial distribution of the lowest energy electrons and holes. Moreover, when the  $E_{\text{field}}$  is between  $-0.06 \text{ V \AA}^{-1}$  and  $-0.34 \text{ V \AA}^{-1}$ , the material manifests a varied direct bandgap which is more favor to optoelectronics and solar cell. Consequently, this vdW heterobilayer with well-controlled manner shows expectation for huge potential in optics and electronics.

## 1. Introduction

Ever since the successful manufacture of isolated graphene was reported,<sup>1</sup> two dimensional (2D) materials have become the subject of extensive research because of their superior optical and electronic properties. Hence, a broad family of 2D materials like graphene, such as BN,<sup>2</sup> transition metal dichalcogenides<sup>3-5</sup> and topological insulators<sup>6-8</sup> etc., has been widely explored to solve that pristine graphene has a zero bandgap. Among them, recently, the SnS<sub>2</sub> 2D films<sup>9,10</sup> have been poured unordinary attentions due to environmentally friendly and earth-abundant. For instance, it was reported that SnS<sub>2</sub> can be used as advance materials for photocatalytic,<sup>11</sup> field effect transistors<sup>12</sup> and anode in lithium batteries.<sup>13</sup> Meanwhile, previous studies on the lamellar semiconductor material of PbI<sub>2</sub> have reported that the freestanding single crystals PbI<sub>2</sub> could be prepared by a facile way.<sup>14</sup> Furthermore, PbI<sub>2</sub> has been demonstrated to be an attractive candidate of thin film transistors and can play the role of a precursor for the organ PbI<sub>2</sub> perovskites employed in highly efficient hybrid solar cells.<sup>15-17</sup> Accordingly, SnS<sub>2</sub> and PbI<sub>2</sub> have promising potential applications in optics and electronics.

For the sake of exploring materials in electronics, optoelectronics and photovoltaics devices, 2D materials can be used as building blocks restacked layer-by-layer in precisely chosen sequences yielding composites with unusual properties.<sup>18,19</sup> A brand new discipline is provided to tailor electronic and optical properties of 2D materials into new physics and device applications owing to their unique crystal properties. For instance, an enterprising and insightful approach has been recently exhibited that an atomically thin p-n diode can be manufactured by a vertically stacked heterobilayer between n-type MoS<sub>2</sub> and p-type WSe<sub>2</sub> slices,<sup>20,21</sup> which will not lead to doping problems.<sup>22</sup> Moreover, properties of vdW heterostructure would be more excellent than building blocks such as the SnS<sub>2</sub>/MoS<sub>2</sub> vdW heterostructure exhibit an obvious photovoltaic effect and possess high mobility ( $27.6 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ ), high on/off ratio ( $>10^6$ ) and high photoresponsivity ( $1.36 \text{ A W}^{-1}$ ), which is more outstanding than SnS<sub>2</sub> and MoS<sub>2</sub>.<sup>23</sup> Thus, the vdW heterostructure with novel electronic and optoelectronic properties will reveal favorable properties and novel phenomena.

It is crucial to modify electronic properties of 2D materials for application in semiconductor devices and the two more effective ways are straining<sup>24,25</sup> and  $E_{\text{field}}$ .<sup>26,27</sup> In this article, we employed an external  $E_{\text{field}}$  to tunable the band structures because of reversibility and easy achievement. A quintessential example should be cited that the bandgap of bilayer graphene can be efficiently switched on *via* applications of electric field

<sup>b</sup>School of Physics and Electronic Engineering, Zhengzhou Normal University, Zhengzhou, Henan 450044, China

because the inversion symmetry of the structure was destroyed.<sup>28,29</sup> The fundamental bandgap of MoS<sub>2</sub>, MoSe<sub>2</sub>, MoTe<sub>2</sub> and WS<sub>2</sub> bilayer structures could be continuously modified with applied electric fields, eventually rendering them metallic.<sup>30–32</sup> Accordingly, utilization of  $E_{\text{field}}$  would lead to the realization of electronic properties engineering of the materials.

The bandgap of homobilayer SnS<sub>2</sub> could be continuously decreased with the electric field as well as different stacks<sup>33</sup> and a robust indirect band structure accompanied with the strength of increasing  $E_{\text{field}}$ . However, it is well known that the electron-hole recombination lifetime of the indirect bandgap semiconductor is longer than direct bandgap leading to lower the luminous efficiency, which is inappropriate for optoelectronic devices. Despite lots of researchers force on the modulation electronic properties of SnS<sub>2</sub> such as doping and strain,<sup>10,12</sup> there is no literature on SnS<sub>2</sub> with a direct bandgap.

In this work, we investigated the vdW heterostructure restacked by SnS<sub>2</sub> monolayer and PbI<sub>2</sub> monolayer to engineer an alternative type of advance optoelectronic material to realize any practical application of 2D vdW p–n junctions. The electronic properties have been systematically studied with external  $E_{\text{field}}$  by theoretical simulation and a well-behaved was found. The features make SnS<sub>2</sub>/PbI<sub>2</sub> vdW heterobilayer a promising material for the advantage optoelectronic devices.

## 2. Theoretical methods

Our calculations were performed based on the density functional theory (DFT) in conjunction with the projector-augmented wave (PAW) potentials<sup>34</sup> as implemented in the Vienna *Ab initio* Simulation Package (VASP).<sup>35,36</sup> The exchange–correlation potentials was described through the Perdew–Burke–Ernzerhof (PBE) functional within the generalized gradient approximation (GGA) formalism.<sup>37</sup> The valence electron configurations for Sn, S, Pb and I were 4d<sup>10</sup>5s<sup>2</sup>5p<sup>2</sup>, 3s<sup>2</sup>3p<sup>4</sup>, 5d<sup>10</sup>6s<sup>2</sup>6p<sup>2</sup> and 5s<sup>2</sup>5p<sup>5</sup>, respectively. The heterobilayer was built by  $\sqrt{7} \times \sqrt{7}$  cells of SnS<sub>2</sub> and 2 × 2 cells of PbI<sub>2</sub>. That a plane wave basis set with a cutoff energy of 480 eV and a 5 × 5 × 1 *k*-points grids determined by a fine grid of gamma-centered Monkhorst–Pack method<sup>38</sup> in the Brillouin zone was found to give good converged results. The atomic structures were relaxed using conjugate gradient algorithm as implemented in the VASP code until the forces on all unconstrained atoms were smaller than 0.01 eV Å<sup>−1</sup>. Moreover, a more precise method for the on-site Coulomb repulsion of Sn 4d and Pb 5d was considered in all calculations for the sake of more accurate bandgap. A PBE+U approach<sup>39</sup> was employed to treat exchange–correlation energy and the choice of  $U = 9$  eV for Sn as well as 8.5 eV for Pb can reproduce the experimental bandgap of SnS<sub>2</sub> and PbI<sub>2</sub>, respectively. Additionally, spin-orbital-coupling<sup>40</sup> was expected to be significant influence on the heavy atoms of lead (Pb), therefore it was considered in all calculation. A vacuum layer of 20 Å along *z* direction was constructed to eliminate the interaction with spurious replica images. The zero damping DFT-D3 method of Grimme<sup>41</sup> was used to account for long range vdW interaction between monolayer SnS<sub>2</sub> and PbI<sub>2</sub>. All of

structural figures and charge density drawings were produced by VESTA package.<sup>42</sup>

## 3. Results and discussion

The schematic illustration of monolayer SnS<sub>2</sub> and PbI<sub>2</sub> is displayed in Fig. 1. Primitive cells are plotted by a black line and a brief look for the vector of lattices is marked. After the total energy optimization, the lattice constants of monolayer SnS<sub>2</sub> and PbI<sub>2</sub> are respectively collected as 3.61 Å and 4.67 Å as exhibited in Table 1, that the agreements with previous studies are preminent.<sup>8,22,32</sup> The properties of monolayer SnS<sub>2</sub> and PbI<sub>2</sub> are intensely sensitive to in-plane strains<sup>43,44</sup> so that the impact of strain on electronic structure should be reduced. To minimize the lattice mismatch between the stacking blocks, the supercell of this heterostructure is built by  $\sqrt{7} \times \sqrt{7}$  of SnS<sub>2</sub> cells and 2 × 2 of PbI<sub>2</sub> cells, which the maximum mismatch for both SnS<sub>2</sub> and PbI<sub>2</sub> lattices is less than 2.3%.

The top and across views of the SnS<sub>2</sub>/PbI<sub>2</sub> vdW heterostructure is presented in Fig. 1(c) and (d). The thicknesses of monolayers and the distance between SnS<sub>2</sub> and PbI<sub>2</sub> single-layer are respectively marked with  $d$  and  $h$  as displayed in Fig. 1(d). The optimized structural parameters and the binding energies are given in Table 1. After fully relaxed, the interlayer distance ( $h = 3.49$  Å) is far greater than the sum of the covalent radii of I and S atom, indicating that the two building blocks are beyond the bonding range. To evaluate the stability, the binding energy ( $\Delta E_{\text{b}}$ ) of SnS<sub>2</sub>/PbI<sub>2</sub> vdW heterobilayer was calculated and defined by,

$$\Delta E_{\text{b}} = (E_{\text{SnS}_2/\text{PbI}_2} - E_{\text{SnS}_2} - E_{\text{PbI}_2})/n, \quad (1)$$

where  $E_{\text{SnS}_2/\text{PbI}_2}$ ,  $E_{\text{SnS}_2}$  and  $E_{\text{PbI}_2}$  represent total energy of the SnS<sub>2</sub>/PbI<sub>2</sub> vdW heterostructure, SnS<sub>2</sub> monolayer and PbI<sub>2</sub> monolayer, respectively. Meanwhile, [SnS<sub>2</sub>] unit cells in the superlattice are marked as  $n$  which equals to seven in this article. By this definition, a negative  $\Delta E_{\text{b}}$  is indicative of that the heterostructure is stable.

Fig. 1 Schematic of the monolayers and the SnS<sub>2</sub>/PbI<sub>2</sub> vdW heterobilayer. Top view of (a) SnS<sub>2</sub> and (b) PbI<sub>2</sub> monolayer. The top (c) and side view (d) of the heterobilayer. Silvery, yellow, dark grey and purple spheres represent Sn, S, Pb and I atoms, respectively.

**Table 1** The lattice constants of SnS<sub>2</sub> monolayer, PbI<sub>2</sub> monolayer and the SnS<sub>2</sub>/PbI<sub>2</sub> vdW heterostructure, respectively

		<i>a</i> (Å)	<i>d</i> (Å)	<i>h</i> (Å)
SnS <sub>2</sub> monolayer		3.61	2.98	
PbI <sub>2</sub> monolayer		4.67	3.72	
The heterostructure	SnS <sub>2</sub> monolayer	9.45	3.03	3.49
	PbI <sub>2</sub> monolayer		3.68	

The binding energy of SnS<sub>2</sub> and PbI<sub>2</sub> vdW heterobilayer is −0.124 eV per SnS<sub>2</sub> unit, which is indicative of a rather weak but stable interaction between the layers. This could be just more evidence for that the interaction between SnS<sub>2</sub> monolayer and PbI<sub>2</sub> monolayer is mainly forced through van der Waals interactions because  $\Delta E_b$  has the same order of magnitude as the other vdW substances, for example, graphite ( $\Delta E_b = -0.10$  eV per C atom),<sup>45</sup> bilayer SnS<sub>2</sub> ( $\Delta E_b = -0.05$  eV per SnS<sub>2</sub> unit),<sup>33</sup> the MoS<sub>2</sub>/PbI<sub>2</sub> heterostructure ( $\Delta E_b = -0.234$  eV per MoS<sub>2</sub> unit)<sup>46</sup> and black phosphorus/MoS<sub>2</sub> heterobilayer ( $\Delta E_b = -0.108$  eV per MoS<sub>2</sub> unit).<sup>47</sup>

We calculate the band structures of monolayer SnS<sub>2</sub> (Fig. 2(a)) and PbI<sub>2</sub> (Fig. 2(b)) as well as the SnS<sub>2</sub> and PbI<sub>2</sub> vdW heterostructure (Fig. 2(c)) to obtain the electronic properties based on PBE+U approach. For SnS<sub>2</sub> monolayer, the fundamental band structure is an indirect bandgap of about 2.22 eV that the valance band maximum (VBM) is extremely close to  $\Gamma$  point and the conduction band minimum (CBM) lies at  $M$  which is close to the reported values.<sup>12,48</sup> Additionally, the smallest gap of PbI<sub>2</sub> monolayer appears between the CBM at  $\Gamma$  and the VBM which medially lies between  $K$  and  $\Gamma$  that the agreements with previous studies are preminent.<sup>43</sup>

In Fig. 2(c), we present the projected band structure of the SnS<sub>2</sub> and PbI<sub>2</sub> in the vdW heterobilayer that the blue lines represent of SnS<sub>2</sub> monolayer and the red lines are for PbI<sub>2</sub>, respectively. As can be seen in Fig. 2(c), the SnS<sub>2</sub> monolayer and PbI<sub>2</sub> monolayer compose a type-II staggered-gap band alignment that the CBM is contributed by SnS<sub>2</sub> whereas the VBM by PbI<sub>2</sub> with a bandgap of about 1.98 eV. In consequence, the Fermi level shifts to the CBM of SnS<sub>2</sub> and VBM of PbI<sub>2</sub> after they compose the heterobilayer. It can be looking forward that the

photoelectric property will be improved distinctively because the lowest energy electron–hole pairs can separate in real space. Compared with the band structure, band alignment of heterostructure are even more important in material and device design. Meanwhile, the work function ( $\Phi = E_{\text{Van}} - E_F$ , where the  $E_{\text{Van}}$  is the vacuum level and the  $E_F$  is the Fermi level, respectively) and band alignment is shown in Fig. 2(d). It is indicated that a type-II band alignment of vdW heterostructure is formed at the SnS<sub>2</sub>/PbI<sub>2</sub> interface which will spontaneously separate the free electrons and holes, enabling the high efficiency optoelectronics and solar energy conversion.

To shed more lights on the nature of the charge transfer between the SnS<sub>2</sub> and PbI<sub>2</sub> layer, the averaged difference electron density of the heterostructure along the  $z$  direction was calculated by the formula

$$\Delta\rho = \int \rho_{\text{SnS}_2/\text{PbI}_2}(x, y, z) dx dy - \int \rho_{\text{SnS}_2}(x, y, z) dx dy - \int \rho_{\text{PbI}_2}(x, y, z) dx dy, \quad (2)$$

where the  $\int \rho_{\text{SnS}_2/\text{PbI}_2}(x, y, z) dx dy$ ,  $\int \rho_{\text{SnS}_2}(x, y, z) dx dy$  and  $\int \rho_{\text{PbI}_2}(x, y, z) dx dy$  are the charge density at the  $(x, y, z)$  point in the SnS<sub>2</sub>/PbI<sub>2</sub> bilayer, SnS<sub>2</sub> and PbI<sub>2</sub> monolayer, respectively. Accordingly, a positive value means electron accumulation and negative for depletion. The result is exhibited in Fig. 3(a), that the vertical blue short dash line means the intermediate position for the interface of the building blocks as well as the positions of Sn, S, Pb and I atomic layers are marked as purple, dark grey, yellow and silvery and short dot lines, respectively. As a result of the interlayer coupling effect, there is an obvious charge accumulation region as the SnS<sub>2</sub>/PbI<sub>2</sub> heterointerface. Moreover, there is a small amount of electrons (about  $0.453 \times 10^{-3}|e|$ ) transferring from PbI<sub>2</sub> to SnS<sub>2</sub> layer, further indicating a weak interlayer coupling between SnS<sub>2</sub> layer and PbI<sub>2</sub> layer. Furthermore, a built-in electrical field formed intrinsic spontaneous of electric polarization is expected and directed from PbI<sub>2</sub> to SnS<sub>2</sub>.

It is crucial to modify electronic properties of 2D materials for application in semiconductor devices so that an external  $E_{\text{field}}$  perpendicular to the heterobilayer is employed. The

**Fig. 2** Electronic band structures of (a) PbI<sub>2</sub>, (b) SnS<sub>2</sub>, (c) The projected band structure as well as schematic of band alignment of SnS<sub>2</sub>/PbI<sub>2</sub> vdW heterostructure (blue and red lines respectively represent for SnS<sub>2</sub> and PbI<sub>2</sub> layer). The Fermi level is set to zero and marked by horizontal blue dotted line. The vacuum level is taken as a reference marked by green horizontal dash.

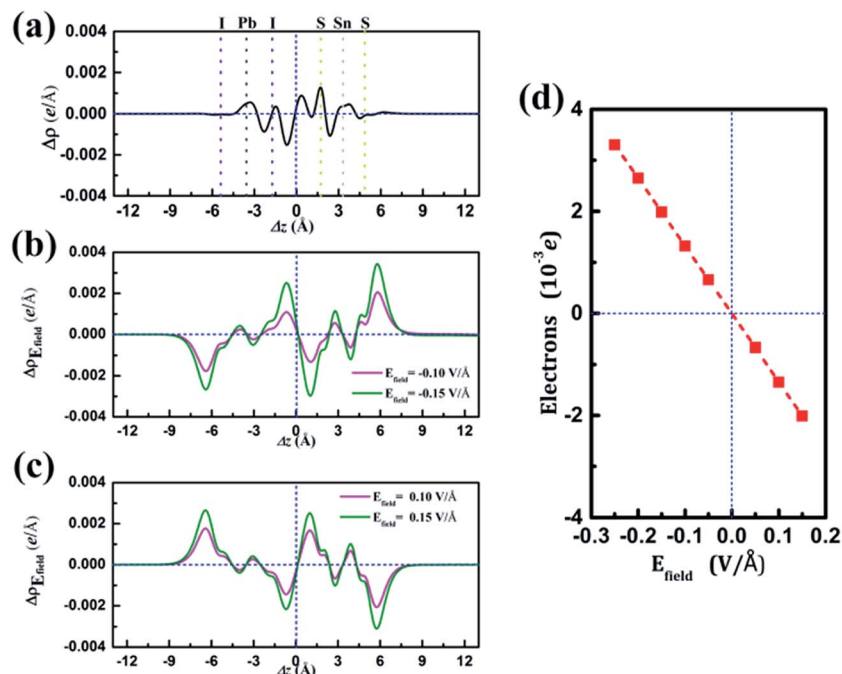

Fig. 3 (a) The averaged difference electron density of SnS<sub>2</sub>/PbI<sub>2</sub> heterostructure along *z* direction. (b) and (c) The integrated charge density difference of the heterobilayer under different external  $E_{\text{field}}$ . (d) The transferred electrons as a function of  $E_{\text{field}}$ . The positive values of electrons in (d) indicate a transferred direction from SnS<sub>2</sub> to PbI<sub>2</sub> layer.

positive direction of  $E_{\text{field}}$  is set from PbI<sub>2</sub> layer to SnS<sub>2</sub> layer. To evaluate the influences of  $E_{\text{field}}$  modulating on the electronic properties of the heterostructure, the integrated charge density difference with  $E_{\text{field}}$  along *z* direction was employed and determined as,

$$\Delta\rho_{E_{\text{field}}} = \int \rho_{\text{SnS}_2/\text{PbI}_2}^{E_{\text{field}} \neq 0}(x, y, z) dx dy - \int \rho_{\text{SnS}_2/\text{PbI}_2}^{E_{\text{field}} = 0}(x, y, z) dx dy, \quad (3)$$

where  $\int \rho_{\text{SnS}_2/\text{PbI}_2}^{E_{\text{field}} \neq 0}(x, y, z) dx dy$  and  $\int \rho_{\text{SnS}_2/\text{PbI}_2}^{E_{\text{field}} = 0}(x, y, z) dx dy$  are the charge density at (*x*, *y*, *z*) point of SnS<sub>2</sub>/PbI<sub>2</sub> heterostructure with and without  $E_{\text{field}}$ . The results are displayed in Fig. 3(b) and (c). It is obvious that the charge redistribution is mainly on the surface of SnS<sub>2</sub> and PbI<sub>2</sub> layers. The positive charges (holes) tend to transfer from SnS<sub>2</sub> layer to PbI<sub>2</sub> layer and negative charges (electrons) transfer from PbI<sub>2</sub> layer to SnS<sub>2</sub> layer in the case of a negative  $E_{\text{field}}$  as well as positive  $E_{\text{field}}$  lead to the opposite direction of charge and hole transfers. Additionally, the amount of transferring electrons depends on the strength of the applied  $E_{\text{field}}$ .

To shed more lights on the charge redistribution with  $E_{\text{field}}$ , the numbers of polarized electrons on the building blocks were obtained through integrating the charge density from the vacuum layer to the intermediate position of the interface of the monolayers as exhibited in Fig. 3(d). The positive value means the electron transfers from SnS<sub>2</sub> layer to PbI<sub>2</sub> layer. The numbers of polarized electrons on the building blocks display a linear evaluation with external  $E_{\text{field}}$  and a transitional on the direction depends on the direction of  $E_{\text{field}}$  is found, which is identical with above analyses. The accumulation of electrons (holes) will lead to the Fermi level down (up)-shifted of SnS<sub>2</sub> and

PbI<sub>2</sub> monolayer which thereby bring about modulation of the band structure. More charge transfer between SnS<sub>2</sub> and PbI<sub>2</sub> layer heralds a stronger interlayer interaction, indicating the shifts of band edges.

This could be graphically explained in Fig. 4(a), which manifests the evolution of the bandgap of SnS<sub>2</sub>/PbI<sub>2</sub> heterostructure as a function of applied  $E_{\text{field}}$ . The bandgap is continuously tuned under the  $E_{\text{field}}$ , eventually achieving a mutation from semiconductor to metal at critical  $E_{\text{field}}$ . The bandgap varies linearly with  $E_{\text{field}}$  indicating a giant Stark effect.<sup>49</sup> It is almost lineally reduced with the strength of  $E_{\text{field}}$  reducing to zero bandgap at the  $E_{\text{field}}$  of about 0.28 V Å<sup>-1</sup> when a forward voltage is applied. For a negative  $E_{\text{field}}$ , the bandgap firstly increases reaching up to 2.19 eV which appears at an  $E_{\text{field}}$  of about -0.03 V Å<sup>-1</sup>. The encouragement of bandgap is due to the presence of intrinsic spontaneous of electric polarization which is opposite to the  $E_{\text{field}}$  and has a superimposing effect on it. Further increases in strength of negative  $E_{\text{field}}$  ( $|E_{\text{field}}| > 0.06$  V Å<sup>-1</sup>) lead to linearly decreases in bandgap and the heterobilayer turns metallic at about -0.34 V Å<sup>-1</sup>.

To gain further insight, band edges dominated by SnS<sub>2</sub> and PbI<sub>2</sub> under various  $E_{\text{field}}$  are calculated and displayed in Fig. 4(b). The CBM and VBM of SnS<sub>2</sub>(PbI<sub>2</sub>) of the vdW heterobilayer are denoted by CBM<sub>SnS<sub>2</sub>(PbI<sub>2</sub>)</sub> and VBM<sub>SnS<sub>2</sub>(PbI<sub>2</sub>)</sub>, respectively. Both the CBM and VBM of SnS<sub>2</sub> decrease linearly with  $E_{\text{field}}$  while the CBM and VBM of PbI<sub>2</sub> manifest a linear increase. The  $E_{\text{field}}$  exerts little influence on the respective bandgaps of SnS<sub>2</sub> and PbI<sub>2</sub>. The bandgap of SnS<sub>2</sub>/PbI<sub>2</sub> heterostructure gives the same variation trend with Fig. 4(a). Additionally, the band alignment conversion from type-II to type-I heterostructure

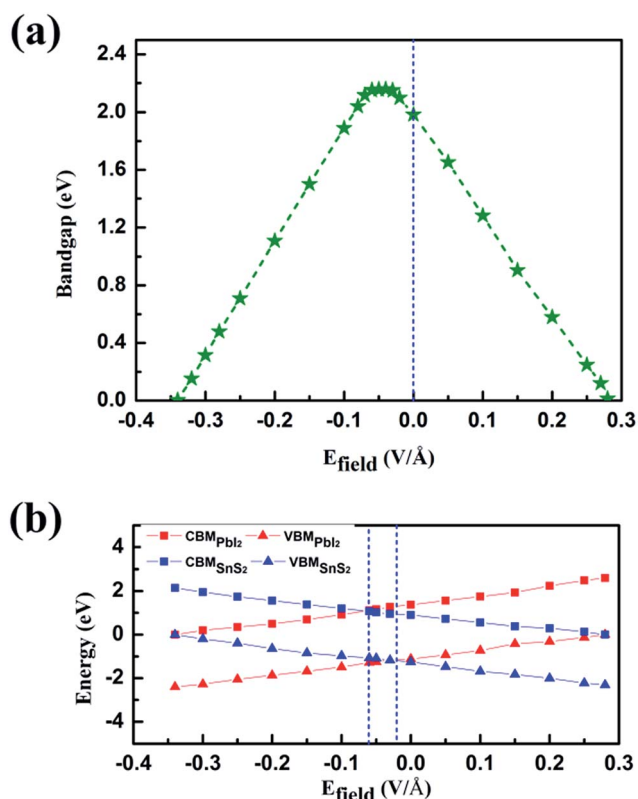

Fig. 4 (a) Bandgap variation with applied  $E_{\text{field}}$  of the  $\text{SnS}_2/\text{PbI}_2$  vdW heterostructure. (b) Evolution of the band edges in  $\text{SnS}_2/\text{PbI}_2$  heterostructure as a function of the  $E_{\text{field}}$ .  $\text{CBM}_{\text{SnS}_2(\text{PbI}_2)}$  and  $\text{VBM}_{\text{SnS}_2(\text{PbI}_2)}$  are the CBM and VBM of  $\text{SnS}_2(\text{PbI}_2)$  in the vdW heterobilayer.

separated by the  $E_{\text{field}}$  about  $-0.03 \text{ V } \text{\AA}^{-1}$  and then from type-I to type-II by about  $-0.06 \text{ V } \text{\AA}^{-1}$ , resulting in different spatial distribution of the lowest energy electrons and holes.

Energy dispersion with and without  $E_{\text{field}}$  is displayed in Fig. 5(a)–(d), respectively. With an  $E_{\text{field}}$  of  $-0.15 \text{ V } \text{\AA}^{-1}$ , the heterobilayer manifests a direct bandgap that both the CBM and VBM are located at  $\Gamma$  point. The direct bandgap semiconductor has a less electron–hole recombination lifetime with a high luminous efficiency which is overwhelmingly suitable for optoelectronic devices. The location of CBM changes from  $\Gamma$  to  $M$  point in the Brillouin zone but the VBM is still at  $\Gamma$  point leading to an indirect bandgap in the case of  $E_{\text{field}} = -0.05 \text{ V } \text{\AA}^{-1}$  as shown in Fig. 5(b). When an  $E_{\text{field}}$  of  $0.15 \text{ V } \text{\AA}^{-1}$  is added to the vdW heterostructure, the band structure manifests an indirect bandgap that the CBM located at  $M$  point and VBM between  $K$  to  $\Gamma$  point (Fig. 5(d)).

The partial charge densities of the heterostructure from CBM and VBM with different  $E_{\text{field}}$  are calculated and summarized in Fig. 5. When the  $\text{SnS}_2/\text{PbI}_2$  vdW heterobilayer subjected to a negative  $E_{\text{field}}$  of  $-0.15 \text{ V } \text{\AA}^{-1}$ , it is clearly shown that the partial charge density from CBM is dominated by Pb atoms and the VBM comes mainly from the  $\text{SnS}_2$  layer, as shown in Fig. 5(a). That is to say, the staggered-gap band alignment be suggestive of a type-II heterojunction. Both the CBM and VBM of the heterobilayer, when the heterobilayer suffered by an  $E_{\text{field}}$  of  $-0.05 \text{ V } \text{\AA}^{-1}$ , are all straddled by  $\text{SnS}_2$  layer (Fig. 5(b)) indicating a type-I heterojunction. When the heterobilayer suffered by the  $E_{\text{field}}$  of  $0 \text{ V } \text{\AA}^{-1}$  or  $0.15 \text{ V } \text{\AA}^{-1}$ , the partial charge density from CBM is dominated by Sn atoms and the VBM by I atomical layer displayed in Fig. 5(c) and (d), respectively. Thus, a type-II

Fig. 5 Band structures and partial charge densities plot for the CBM and VBM of the  $\text{SnS}_2/\text{PbI}_2$  vdW heterostructure with and without  $E_{\text{field}}$ : (a)  $E_{\text{field}} = -0.15 \text{ V } \text{\AA}^{-1}$ , (b)  $E_{\text{field}} = -0.05 \text{ V } \text{\AA}^{-1}$ , (c)  $E_{\text{field}} = 0 \text{ V } \text{\AA}^{-1}$ , and (d)  $E_{\text{field}} = 0.15 \text{ V } \text{\AA}^{-1}$ . All isosurfaces of this text are set to  $0.004 \text{ e } \text{\AA}^{-3}$ .

Fig. 6 Band alignments of the SnS<sub>2</sub>/PbI<sub>2</sub> vdW heterobilayer under different  $E_{\text{field}}$ .

staggered-gap band alignment is obtained with an alternation of CBM and VBM between the monolayer SnS<sub>2</sub> and PbI<sub>2</sub>. Briefly, the band structures can be effectively modulated by an external electric field.

Similar evidence also comes from the band alignment of SnS<sub>2</sub>/PbI<sub>2</sub> heterostructure under various  $E_{\text{field}}$ , as seen in Fig. 6. The  $E_{\text{f-SnS}_2(\text{PbI}_2)}$  indicate the quasi-Fermi level of SnS<sub>2</sub>(PbI<sub>2</sub>) in the vdW heterobilayer.  $V_{\text{D}}$  denote the conduction band offset in the SnS<sub>2</sub>/PbI<sub>2</sub> heterostructure without an  $E_{\text{field}}$  as well as  $V = E_{\text{field}} \times d$  is the external electric potential, which leads to the divergence of the quasi-Fermi levels. The interlayer distance is marked with  $d$ , which is a constant in this case. When the SnS<sub>2</sub>/PbI<sub>2</sub> vdW heterostructure subjected to a negative  $E_{\text{field}}$ , the bandgap varies with  $E_{\text{field}}$  in the following function:

$$E_{\text{g}} = E_{\text{g}(\text{SnS}_2)} - e(V_{\text{D}} - V) = E_{\text{g}(\text{SnS}_2)} - eV_{\text{D}} + eE_{\text{field}} \times d. \quad (4)$$

The maximum bandgap is obtained when the  $E_{\text{field}}$  reaches to  $-0.03 \text{ V \AA}^{-1}$ . Even the electric field increasing to  $-0.06 \text{ V \AA}^{-1}$ , both the CBM and VBM of the heterobilayer are all straddled by SnS<sub>2</sub> layer. So, bandgap can be obtained as,

$$E_{\text{g}} = E_{\text{g}(\text{SnS}_2)} \approx 2.19 \text{ eV}.$$

Under circumstances of  $E_{\text{field}}$  greater than  $0.06 \text{ V \AA}^{-1}$  along the negative direction, the bandgap varies as the function:

$$E_{\text{g}} = E_{\text{g}(\text{SnS}_2)} - e(E_{\text{field}} - 0.06)d.$$

The linear evaluations of bandgap with the strength of  $E_{\text{field}}$  are obtained as the  $E_{\text{g}(\text{SnS}_2)}$  and  $e$  is constant. Meanwhile, the varied relationship between bandgap and  $E_{\text{field}}$  shares the same evidence of the giant Stark effect.

## 4. Conclusions

In summary, a vdW heterostructure of SnS<sub>2</sub> and PbI<sub>2</sub> has been theoretically simulated and the heterobilayer has a well-

behaved electronic property under an external  $E_{\text{field}}$ . A type-II staggered-gap band alignment is constituted which the spatial separation of the lowest energy electron-hole pairs can be actualized. When suffered under an external  $E_{\text{field}}$ , the charge redistribution is mainly on the surface of SnS<sub>2</sub> and PbI<sub>2</sub> layers and the numbers of polarized electrons on the building blocks display a linear evaluation with external  $E_{\text{field}}$ . Meanwhile, the transitional direction depends on the direction of  $E_{\text{field}}$ . The external  $E_{\text{field}}$  not only influences the band structure which changes from semiconductor to metal but also forces on band alignment which experiences a conversion between type-I straddling-band alignment type-II broken-gap, leading to a different spatial distribution of the lowest energy electrons and holes. A direct bandgap of the heterobilayer is found among  $-0.06 \text{ V \AA}^{-1}$  and  $-0.34 \text{ V \AA}^{-1}$ . This work could bring forward a new perspective on advantage optoelectronics devices with a well- $E_{\text{field}}$ -controlled manner by using SnS<sub>2</sub>/PbI<sub>2</sub> vdW heterostructure.
