# Synthesis and biological evaluation of (*E*)-4-(3-arylvinyl-1*H*-indazol-6-yl)pyrimidin-2-amine derivatives as PLK4 inhibitors for the treatment of breast cancer†

Zhihao Liu,‡ Qian Lei,‡ Wei Wei, Lu Xiong, Yaojie Shi, Guoyi Yan, Chao Gao, Tinghong Ye, Ningyu Wang\* and Luoting Yu \*

Polo-like kinase 4 (PLK4), a vital regulator of centriole duplication, is important for maintaining genome stability. Dysregulation of PLK4 has been found in several human cancers and is associated with a predisposition to tumorigenesis. Herein, we describe the discovery of (*E*)-4-(3-arylvinyl-1*H*-indazol-6-yl)pyrimidin-2-amine derivatives as potent PLK4 inhibitors with more concise structure using a scaffold hopping strategy. SAR exploration and preliminary assessment identified **14i** as a new PLK4 inhibitor which displayed excellent potency *in vitro*. **14i** could inhibit the activity of PLK4, perturb centriole replication, result in mitosis disorder and induce cell apoptosis in breast cancer cells. Moreover **14i** demonstrated significant antitumor efficacy in the MDA-MB-468 and MDA-MB-231 xenograft models. This study suggested that this concise chemotype would represent a promising scaffold of PLK4 inhibitors for cancer therapy and **14i** would be an attractive lead compound for further optimization and evaluation.

## Introduction

The polo-like kinase family belongs to a class of highly conserved serine/threonine kinases which consists of five subtypes in mammals: PLK1, PLK2/Snk, PLK3/Fnk/Prk, PLK4/Sak and PLK5.<sup>1</sup> They are involved in the regulation of cell cycle progression, including intersection of mitotic, spindle formation, cytokinesis, and are often deregulated in cancer.<sup>2</sup> The N-terminus of PLKs has a highly homologous serine/threonine kinase catalytic domain except PLK5;<sup>3</sup> and the C-terminus of PLKs contains one or two signature polo-box domains which are related to the location of PLKs into specific mitotic subcellular structures during mitosis.<sup>4,5</sup>

One of the PLKs members, PLK4, shows obviously differences compared with other PLKs at the amino acid sequence level which contains only one polo-box domain instead of two.<sup>6,7</sup> PLK4 is a main regulator of centriole duplication during mitosis and cell cycle.<sup>8–10</sup> PLK4 is usually expressed in proliferative tissues with low abundance, but is aberrantly expressed in many tumor types, especially in breast cancer.<sup>11</sup> High PLK4 levels in breast cancers are associated with poor prognosis and survival.<sup>12–14</sup>

Dysregulation of PLK4 often causes disorder of centrosome duplication and aneuploidy formation, thereby promoting genomic instability which is a characteristic observed in many types of cancers.<sup>15,16</sup> Depletion of PLK4 by RNA interference in breast cancer cells and xenografts induces cell apoptosis and tumor growth suppression.<sup>16</sup> Besides, PLK4 is crucial to PTEN-deficient cancer cells for survival suggesting that there is a synthetic lethal interaction between PLK4 and PTEN in breast cancer cells.<sup>17,18</sup> Thus, PLK4 could be a potential target for breast cancer and draw our attention to discover PLK4 inhibitors as candidates against breast cancer.

Some typical PLK4 inhibitors are shown in Fig. 1. Multi-kinase inhibitor **1** (R1530) has been shown to be potent against PLK4 with an IC<sub>50</sub> value of 6 nM. It could promote cancer cells genomic instability and facilitate cancer cells sensitive to chemotherapy.<sup>19</sup> **2** (Centrinone), a selective PLK4 inhibitor, could result in a p53-dependent cell cycle arrest in G<sub>1</sub>.<sup>20</sup> And **3** (Axitinib), a well-known pan-VEGFR inhibitor, has been approved for renal cell carcinoma (RCC) by FDA and demonstrated collateral inhibitory activity against PLK4 with a K<sub>i</sub> value of 4.2 nM.<sup>21</sup> Recently, **4** (CFI-400437) with a scaffold of (*E*)-3-((1*H*-indazol-6-yl)methylene)indolin-2-ones was reported to be a PLK4 inhibitor with an IC<sub>50</sub> value of 6 nM,<sup>22</sup> and its spirooxindole counterparts **5**, **6**, and **7** exhibited excellent selectivity and potency.<sup>23–25</sup> **6** (CFI-400945) has demonstrated significant efficacy in animal models of breast cancer, colorectal cancer and pancreatic cancer, especially in PTEN-deficient cancer patient-derived xenografts.<sup>17,24,26</sup>

Fig. 1 Chemical structures of representative PLK4 inhibitors.

To our knowledge, the reported scaffolds of PLK4 inhibitors are not diverse. What is more, although some bioactive molecules such as **1** (R1530) and **3** (Axitinib) demonstrated good inhibitory activity against PLK4, their main targets are not PLK4. Despite preferentially isolated as the *E*-isomer, the indazolymethyleneindolinone compound **4** has the potential to isomerize *in vivo*.<sup>23</sup> **5**, **6**, and **7**, as the spirooxindole counterparts of **4**, own improved configurational stability and physicochemical properties, but their synthesis and purification are more complicated due to the spirooxindole motif with multiple chiral centers.<sup>27</sup> Based on above status quo, we wished to explore a more concise scaffold of selective PLK4 inhibitors.

We firstly investigated the co-crystallization structure (PDB code 4JXF) to understand interactions between **5** and PLK4 kinase domain (Fig. 2). As a hinge binder, indazole ring of **5** formed two hydrogen bonds with the backbone carbonyl of Cys92 and NH of Glu90 in the hinge region. The arylvinyl group potentially fit into the solvent-exposed side of the adenine binding pocket, and the aryl fragment had a strong  $\pi$ -cation interaction with amino of Arg28. It is notable that all of **3**, **4**, **6** have the same motif of (*E*)-3-arylvinyl-1*H*-indazole as **5**. Moreover, the carbonyl and NH of oxindole in **5** could form hydrogen bonds with side chain of Lys41 and the backbone carbonyl of Gln160, respectively. And **3**, **4**, **6** also have corresponding fragments to

Fig. 2 X-ray crystal structure of **5** in the active site of PLK4 with interactions to the key residues (PDB code 4JXF).

interact potentially with both these two amino acid residues (Fig. 3). Hence, we speculated that **3–6** might interact with PLK4 kinase domain in the same binding mode.

Based on above analyses, to quest for a new and concise chemotype of PLK4 inhibitors, we kept (*E*)-3-arylvinyl-1*H*-indazole motif as hinge binder and focused on utilizing scaffold hopping strategy to simplify the skeletons at 6-position of indazole in **3–6** simultaneously retaining pharmacophores which could form H-bonds with Lys41 and Gln160 in our pre-conceived scaffold. After careful consideration, we cautiously incorporated 2-aminepyrimidin-4-yl at 6-position of indazole in order to facilitate interactions between compounds and PLK4 (Fig. 3). Herein we report the design, synthesis and biology evaluation of (*E*)-4-(3-arylvinyl-1*H*-indazol-6-yl)pyrimidin-2-amine derivatives as potent PLK4 inhibitors.

## Results and discussion

### Synthesis

The synthesis of target compounds **14a–14y** and **15a–15d** is depicted in Scheme 1. Commercially available 6-bromo-1*H*-indazoles **8a–8b** were reacted with bis(pinacolato)diboron using Pd(dppf)Cl<sub>2</sub> and potassium acetate in dioxane at 90 °C respectively to afford corresponding boronic acid pinacol esters **9a–9b**. Suzuki coupling of **9a–9b** with **10a–10c** respectively provided products **11a–11d**. Then iodination of **11a–11d** was carried out in DMF at 60 °C overnight and provided a good yield of intermediates **12a–12d**. At last, Suzuki coupling of **12a–12d** with *trans*-hetarylvinylboronates **13a–13y** using Pd(dppf)Cl<sub>2</sub> and cesium carbonate afforded target products **14a–14y** and **15a–15d**.

### Study on SAR

The title compounds were evaluated for their PLK4 potency as well as anti-proliferative potencies against MDA-MB-231 and MDA-MB-468 cell lines, and **3** (Axitinib) was used as a positive control. Axitinib demonstrated PLK4 potency with an IC<sub>50</sub> value of 41.3 nM and moderate anti-proliferative activities against MDA-MB-231 and MDA-MB-468 cell lines. The SAR study began with the terminal aryl group of arylvinyl indazole motif. Compared with **3** (Axitinib), **14a** containing a single phenyl displayed moderate PLK4 potency with an IC<sub>50</sub> value of 74.9 nM, and it also exhibited anti-proliferative activities against MDA-MB-231 and MDA-MB-468 cell lines (IC<sub>50</sub> = 6.2 and 8.7  $\mu$ M, respectively), implying that our scaffold hopping strategy was feasible. Incorporation of a methoxy group at the 4-position of phenyl ring in **14a** improved PLK4 potency but its cellular activity declined (**14b**), 3-methylamino substituted analogue **14c** showed similar PLK4 potency with **14a**. The phenyl ring in **14a** replaced with indole (**14d**) resulted in a dramatic drop in PLK4 potency although its cellular activity improved slightly. Substituents on *para*-position of the phenyl ring with hydrophilic groups such as morpholino (**14e**) and *N*-methylpiperazine (**14f**) improved both PLK4 and cellular activities dramatically. The same tendency could also be observed in benzyl analogues **14g**, **14h** and **14i**. However, *meta*-substituted phenyl analogues (**14j**, **14k**) exhibited declined PLK4 and cellular activities,

Fig. 3 Designed strategy of title molecules.

Scheme 1 Synthetic route of title compounds **14a–14y**, **15a–15d**. Reagents and conditions: (a) bis(Pinacolato)diboron, AcOK, Pd(dppf)Cl<sub>2</sub>, dioxane, 90 °C; (b) Pd(dppf)Cl<sub>2</sub>, K<sub>2</sub>CO<sub>3</sub>, dioxane : H<sub>2</sub>O = 4 : 1, 95 °C; (c) I<sub>2</sub>, K<sub>2</sub>CO<sub>3</sub>, DMF, 60 °C; (d) Pd(dppf)Cl<sub>2</sub>, Cs<sub>2</sub>CO<sub>3</sub>, dioxane : H<sub>2</sub>O = 4 : 1, 100 °C.

suggesting that the orientation of hydrophilic groups is very important for the interaction with PLK4.

The pyridin-3(or 4)-yl analogues **14l** and **14m** were slightly better than **14a** in activity. The H atom at 2-position of pyridine in **14m** replaced with morpholino group (**14n**) or piperazinyl group (**14o**) improved the activity, but both PLK4 and cellular potencies declined with the increasing size of substituents, as exemplified by the *N*-methylpiperazinyl (**14p**) and *N*-Bocpiperazinyl (**14q**) analogues, suggesting a suitable size of group on this position was favorable. Among these compounds, **14i** demonstrated excellent inhibitory activity against PLK4 (IC<sub>50</sub> = 11.2 nM) and good potencies against MDA-MB-231 and MDA-

MB-468 cell lines (IC<sub>50</sub> = 0.09 and 0.06 μM, respectively). Then the influence of substituents on 2- and 3-position of the phenyl ring in **14i** was investigated. Introduction of fluorine atom (**14r** & **14v**), chlorine atom (**14s** & **14w**), methyl group (**14t** & **14x**) and methoxy (**14u** & **14y**) on 2-position or 3-position impaired the enzymatic potency to the same extent, but a sharp loss of cellular potency was observed with respect to the 2-substituted groups (**14r–14u**). These results indicated it is the steric effect rather than the electric effect of substituents on the phenyl ring that was crucial to the PLK4 potency, because the hydrophobic pocket near the phenyl ring might be too narrow to accommodate any bulky substituents (Table 1).

Next, we investigated the influence of substituents on pyrimidin-2-amine and 5-position of indazole ring based on the structure of **14i** (Table 2). The acetamino analogues of **14i** or **14r** (**15a**, **15b**) and the methylamino analogue of **14i** (**15c**) were slightly less potent than their corresponding counterparts, suggesting that substituents on this position might be tolerated. Introduction of methyl group at 5-position of indazole ring (**15d**) resulted in a dramatic drop in PLK4 potency ( $IC_{50} = 956$  nM) and antiproliferative activities against MDA-MB-231 and MDA-MB-468 cell lines ( $IC_{50} = 8.60$  and  $5.43$   $\mu$ M, respectively). Interestingly, almost all of these compounds showed better

anti-proliferative effects against MDA-MB-468 (PTEN-deficient cancer cells) than MDA-MB-231 (PTEN-wild type cancer cells), which implicated that PTEN deficient breast cancer cells could be more sensitive to PLK4 inhibitors like **14i** because of the synthetic lethal interaction between PLK4 and PTEN.

### Solubility, Clog P and LLE evaluation

Due to the preference of *in vitro* enzymatic and cellular potencies, compounds **14i**, **14r**, and **15a** were selected to evaluate their solubility in water under different pH. And another two

important parameters of drug-likeness, Clog *P* and LLE (ligand-lipophilicity efficiency), were also calculated<sup>28</sup> (Table 3).

Both compounds **14i** and **15a** exhibited comparable Clog *P* and LLE, as well as solubility in H<sub>2</sub>O, which were much better than **14r**. **14i** was finally selected for further evaluation because of its excellent *in vitro* activity and molecular properties.

Entry	Inh% (100 nM)			
	PLK1	PLK2	PLK3	PLK4
14i	3.59	45.08	2.99	96.21

<sup>a</sup> Note: all compounds were tested at ATP concentration of 10 μM. The percent of inhibition is an average of two independent titrations. PLK5 does not have kinase domain, so it wasn't tested.

Besides, **14i** also exhibited good selectivity for PLK4 over other members of polo-like kinase family (Table 4).

#### Molecular docking of 14i with PLK4

To understand the interaction of (*E*)-4-(3-arylvinyl-1*H*-indazol-6-yl)pyrimidin-2-amine derivatives with PLK4, we modelled the binding mode of **14i** in the ATP pocket using a reported crystal structure of the PLK4 kinase domain (PDB ID: 4JXF). As shown in Fig. 4, **14i** maintained H-bonding interactions with PLK4 at the backbone carbonyl of Cys92 and NH of Glu90 in the hinge region. Interestingly, unlike **5**, the amino group of **14i** formed two hydrogen bonds with the backbone carbonyls of Gln160 and Ala153, and the N atom of 1-pyrimidine in **14i** had an

Fig. 4 Proposed binding mode of compound **14i** to the PLK4 kinase domain.

interaction with crystalline water (HOH 424) instead of forming H-bond with Lys41. Furthermore, *trans*-arylvinyl group in **14i** potentially extended to the solvent-exposed side. Overall, **14i** could fit well into the ATP pocket of PLK4, which enable it to be a potent PLK4 inhibitor.

### Inhibition of centriole duplication and mitosis by **14i**

Because of the crucial role of PLK4 in centriole duplication, we examined the effect of **14i** on centriole duplication in MDA-MB-468 and MDA-MB-231 cell lines by immunostaining DAPI, centrin2 and  $\gamma$ -tubulin to visualize cell nucleus (blue), centriole (green) and mitotic spindle (red) respectively. After 48 h

exposure with **14i**, cells with disordered centrosome replication increased in a dose-dependent manner (Fig. 5A), and 0.5  $\mu$ M of **14i** distinctly inhibited centrosome replication (Fig. 5B).

By analysis of DNA content of MDA-MB-468 and MDA-MB-231 cells using flow cytometry, we found **14i** induced polyploid formation in a dose-dependent manner (Fig. 6A), suggesting that **14i** could result in mitotic disorder and promote genomic instability. Moreover, immunoblot analysis displayed the increase of activated cleaved-caspase-3 which represents the activation of apoptotic pathways and the reduction of P-H3 which indicates the unsmooth progression of mitosis in a dose dependent manner after treated with **14i** (Fig. 6B and C). Overall, **14i** inhibited the activity of PLK4 thereby perturb the centriole

Fig. 5 (A) Cell numbers of abnormal centrosome replication after treated with **14i**. (B) Effects of **14i** on perturbing centrosome replication by immunofluorescence. MDA-MB-468 and MDA-MB-231 cells were treated with **14i** or DMSO for 48 h. Cells were stained with centrin2,  $\gamma$ -tubulin, and DAPI. Insets show higher magnification views of the centrioles (boxed regions).

replication and led to disorder of mitosis, which further induced cell apoptosis in MDA-MB-468 and MDA-MB-231 cells.

### *In vivo* antitumor activity of 14i

We finally evaluated the *in vivo* antitumor activity of compound 14i in MDA-MB-468 (PTEN-deficient breast cancer cells) and

MDA-MB-231 (PTEN-wild type breast cancer cells) xenograft models. Compound 14i was administered orally at doses of 30 mg kg<sup>-1</sup> or 90 mg kg<sup>-1</sup> once daily for 18 consecutive days. The results showed that 14i significantly suppressed tumor growth in MDA-MB-468 and MDA-MB-231 xenograft models. Compared with MDA-MB-231 xenograft model, the tumor growth inhibition rate (TGI) of MDA-MB-468 xenograft was

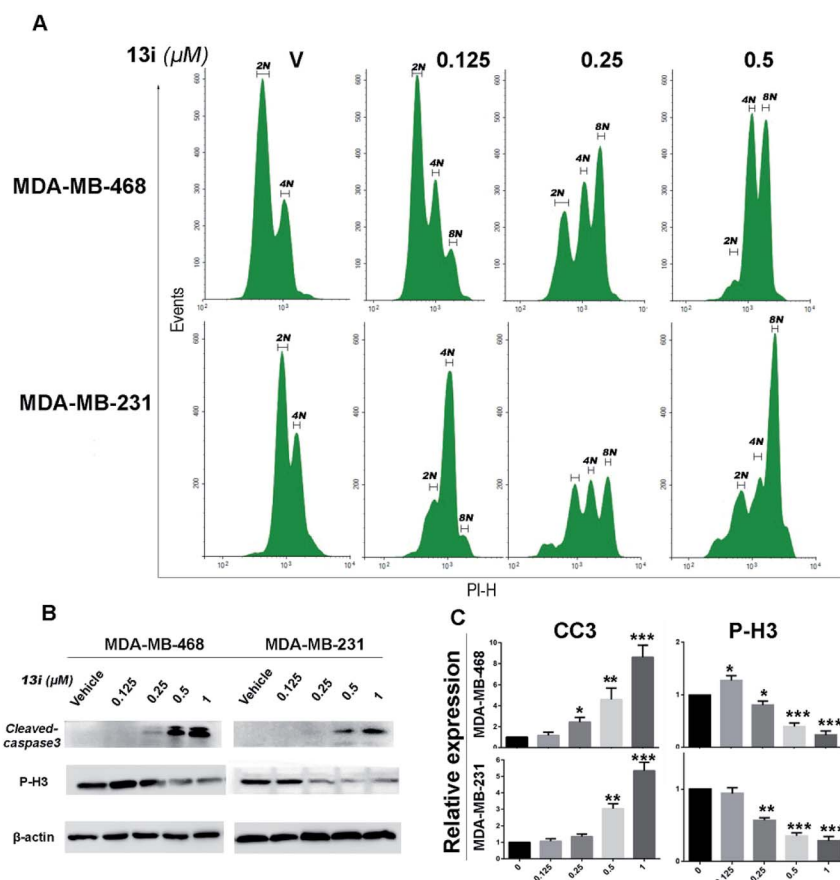

Fig. 6 (A) DNA content analysis by flow cytometry. MDA-MB-468 and MDA-MB-231 cells were treated with 14i or DMSO for 48 h prior to staining with propidium iodide. (B) and (C) MDA-MB-468 and MDA-MB-231 cells lysates were analyzed by immunoblot analysis with antibodies against P-H3 and CC3 (cleaved-caspase-3).

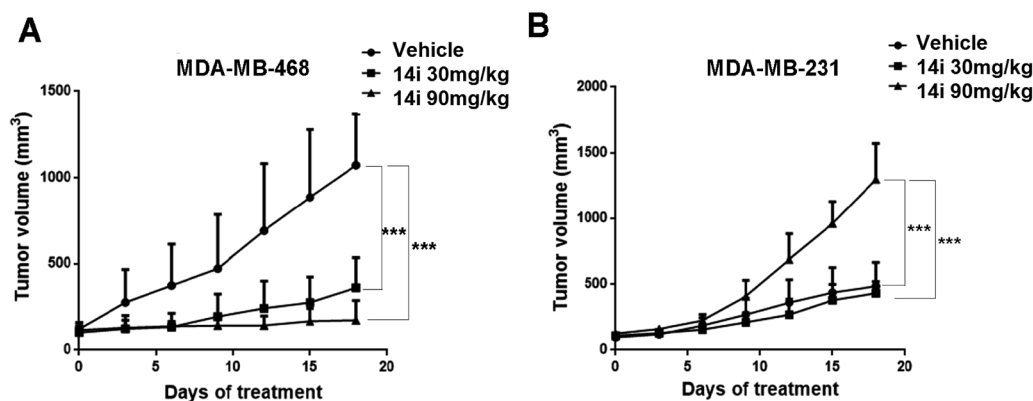

Fig. 7 *In vivo* antitumor efficacy of 14i against MDA-MB-468 (A) and MDA-MB-231(B) tumor xenograft models (5 mice per group). Points indicate mean tumor volume (mm<sup>3</sup>); bars indicate SD.

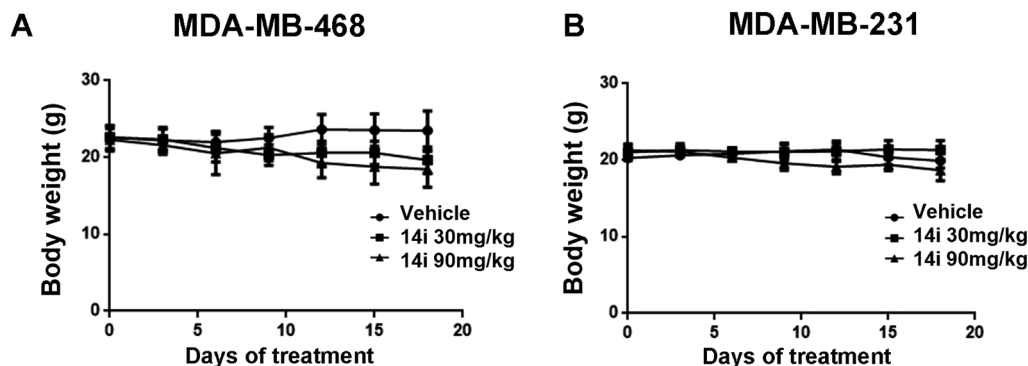

Fig. 8 Body weight measurements *in vivo* antitumor experiments. Note: results are expressed as the mean  $\pm$  SEM ( $n = 5$  for the inhibitor-treated group,  $n = 5$  for the vehicle control group).

much higher, with TGI of 83.1% versus 67.6% and 68.3% versus 63.9% at the doses of 30 mg kg<sup>-1</sup> and 90 mg kg<sup>-1</sup> respectively (Fig. 7), which also confirmed that PTEN-deficient tumors were susceptible to PLK4 inhibitors *in vivo*. Moreover, no significant body weight loss was observed at both doses (Fig. 8).

## Conclusion

In summary, using scaffold hopping strategy, we discovered (*E*)-4-(3-arylviny-1*H*-indazol-6-yl)pyrimidin-2-amine derivatives as a more concise chemotype of PLK4 inhibitors. SAR explorations and preliminary physicochemical properties assessment led to the identification of **14i** as a new PLK4 inhibitor with potent PLK4 activity (IC<sub>50</sub> = 11.2 nM) and significant antiproliferative effects (MDA-MB-231 IC<sub>50</sub> = 0.09 and MDA-MB-468 IC<sub>50</sub> = 0.06  $\mu$ M, respectively). Besides, **14i** exhibited good selectivity for PLK4 over other members of polo-like kinase family. Furthermore, **14i** could perturb the centriole replication and induce disorder of mitosis as well as cancer cells apoptosis. Moreover, **14i** demonstrated significant antitumor efficacy in the MDA-MB-468 and MDA-MB-231 xenograft models. All these data indicated that this chemotype would be a promising starting point for the development of PLK4 inhibitors as anticancer agents and **14i** would be an attractive lead compound for further optimization and evaluation.

## Experimental

### Synthesis of 9a–9b

To a solution of **8a–8b** (40 mmol), bis(pinacolato)-diboron (15.2 g, 60 mmol) and KOAc (7.84 g, 80 mmol) in 1,4-dioxane (100 mL), Pd(dppf)Cl<sub>2</sub> (2 mmol) was added and the mixture was degassed for 5 min. The mixture was heated to 90 °C for 8 h and cooled to r.t. The mixture was diluted with ethyl acetate and filtered through celite. The filtrate was washed successively with water and brine, dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated. The residue was purified by chromatography eluting with Pet : EtOAc = 2.5 : 1 to give products **9a–9b**.

### Synthesis of 11a–11d

To a solution of **9a–9b** (15 mmol), **10a–10c** (12.5 mmol) and KOAc (30 mmol) in 1,4-dioxane (100 mL), Pd(dppf)Cl<sub>2</sub> (0.62

mmol) was added and the mixture was degassed for 5 min. The mixture was heated to 100 °C for 3 h and cooled to r.t. The mixture was diluted with ethyl acetate and filtered through celite. The filtrate was washed successively with water and brine, dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated. The residue was purified by chromatography eluting with DCM : CH<sub>3</sub>OH = 12 : 1 to afford products **11a–11d**.

### Synthesis of 12a–12d

**11a–11d** (8.0 mmol) and K<sub>2</sub>CO<sub>3</sub> (16 mmol) were combined in DMF (15 mL), and I<sub>2</sub> (16 mmol) dissolved in DMF (2 mL) was added dropwise to the mixture, then stirred 10 hours at 65 °C. The reaction was then poured into a solution of sodium dithionite (3.0 g) and K<sub>2</sub>CO<sub>3</sub> (1.1 g) in water (50 mL). A white precipitate formed and was stirred at room temperature for 30 min. Product was isolated by filtration to give **12a–12d**.

### Synthesis of 14a–14y, 15a–15d

To a solution of **12a–12d** (0.36 mmol), *trans*-arylvinyboronates or *trans*-hetarylvinyboronates **13a–13y** (0.43 mmol) and cesium carbonate (0.72 mmol) in 1,4-dioxane : H<sub>2</sub>O = 4 : 1 (15 mL), Pd(dppf)Cl<sub>2</sub> (0.04 mmol) was added and the mixture was degassed for 5 min. The mixture was heated to 100 °C for 8 h and cooled to r.t. The mixture was diluted with ethyl acetate and filtered through celite. The filtrate was washed successively with water and brine, dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated. The residue was purified by chromatography eluting with DCM : CH<sub>3</sub>OH = 10 : 1 to afford the title compounds **14a–14y, 15a–15d**.

### Kinase inhibition assays

Kinase inhibition profiles were obtained using Kinase Profiler services provided by Reaction Biology Corporation, and ATP concentrations used are the ATP *K<sub>m</sub>* of corresponding kinases. Compounds were tested in a 10-dose IC<sub>50</sub> mode with 3-fold serial dilution starting at 10  $\mu$ M.

### Cell lines and cell culture conditions

All of cell lines used were purchased from American Type Culture Collection (ATCC, Manassas, VA, USA). All of them were

cultured in RPIM 1640 or Iscove's Modified Dulbecco's Medium supplemented with 10% fetal bovine serum (FBS, Gibco, Auckland, N.Z.), penicillin-streptomycin (Life Technologies), and 4 mM L-glutamine. The cell lines were cultured in a humidified atmosphere with 5% CO<sub>2</sub> at 37 °C.

### Cell viability assay

The cell viability treated with the compounds described above was measured by MTT assay. 100 μL of medium containing various concentrations of compound was added to 96-well micro-plates, then cells were seeded in each well at a density of 5–10 × 10<sup>4</sup> cells. After cultured for 72 h, the cells were added 20 μL MTT solution (5 mg mL<sup>-1</sup>) and incubated for another 2–4 h at 37 °C. When reached the appropriate time, the formazan crystal formed by living cells was dissolved with 50 μL of the 20% SDS solution overnight. Then, the optical density was measured using Spectra MAX M5 micro-plate spectrophotometer (Molecular Devices) at 570 nm and the IC<sub>50</sub> values were carried out in Graphpad Prism 5 (GraphPad Software Inc.).

### Western blot analysis

The tumor cells MDA-MB-231 and MDA-MB-468 were incubated in medium containing different concentration of **14i** for 48 h. Then harvested cells washed by PBS twice were lysed in RIPA buffer (Byotime, Beijing, China) for 20 min, then ultrasonicated and centrifugated. The protein concentrations were measured and equalized before loading. Protein was separated by SDS-PAGE gels. After electrophoresis, protein was transferred onto polyvinylidene fluoride membranes (Millipore), blocked in 5% non-fat milk for 2 h, washed in TBS-T and incubated with specific antibodies (Cell Signaling Technology) overnight at 4 °C. After incubated with the relevant secondary antibodies, the reactive bands were detected using an enhanced chemiluminescence kit (Millipore).

### Immunofluorescence analysis

For immunofluorescence staining, the treated cancer cells in 8 well chamber slides (Millipore) were washed twice in PBS and fixed in 4% paraformaldehyde for 15 min, then cells were blocked in 1% BSA for 1 h at room temperature. Primary antibody in block buffer was added to cells overnight at 4 °C and washed 3 times by PBS. Goat anti-rabbit and goat anti-mouse secondary antibodies conjugated to FITC and Alexa 594 were used to detect primary antibodies. After washed twice with PBS, the cells were counterstained with DAPI, and the images were captured using a Leica confocal microscope equipped with a Leica X63oil-immersion objective.

### Cell cycle analysis

For the cell cycle analysis, the **14i**-treated cells were fixed and stained with PI staining solution for 5 min in the dark and then detected using flow cytometry (FCM). The data were analyzed using the NovoExpress software.

### Subcutaneous xenograft models

All animal experiments have been approved by the Institutional Animal Care and Treatment Committee of Sichuan University in China (Permit number: 20160188) and were carried out in accordance with the approved guidelines. Six-week-old female BALB/c nude mice were purchased from HFK Biotechnology Company (Beijing, China). Tumors were first prepared by subcutaneously implanting 1 × 10<sup>7</sup> cells/0.1 mL into the right flank region of mice. When the volume reached 200 mm<sup>3</sup>, tumors were dissected into fragments of approximated 10–20 mm<sup>3</sup> and subsequently implanted into hind flank region of BALB/c nude mice. When the tumor reached 80–110 mm<sup>3</sup>, mice were selected and randomized into groups for further study (*n* = 5). Mice were given **14i** and blank solvent once daily by oral gavage. Tumor size was monitored every 3 days using calipers and the volume was calculated using the following formula: tumor volume = length × width<sup>2</sup> × 0.5.

### Solubility test<sup>29</sup>

The production of test solution: each compound was added in excess to 1000 μL solvent. The drug suspensions were placed in ultrasound for 15 min followed by filtration to get the saturated solution. Then the test solutions were obtained by diluting the saturated solution 100 times.

The production of reference solution: adding accurate 2.000 mg (*m<sub>r</sub>*) compound into 1000 μL methanol. The solutions were placed in ultrasound for 15 min to dissolve completely. Then filtered and the reference solutions were obtained by diluting the filter liquor 100 times.

The concentration of each sample was measured with HPLC-UV-vis apparatus. The test condition is as follows:

Chromatographic column: Venusil XBP (C18) 5 μm 150 Å 4.6 × 250 mm.

Mobile phase: methanol (A) and pH = 6.8H<sub>2</sub>O (B)

Injection volumes: 40 μL per injection.

Column temperature: 30 °C.

Pressure: 120 Pa.

Flow rate: 1.00 mL min<sup>-1</sup>.

The calculation formula of solubility is as follows:

$$C = (m_r \times A_t) / (A_r \times 1000)$$

*A<sub>t</sub>* and *A<sub>r</sub>* are respectively refer to the area of test solution's chromatographic peak and the area of reference solution's chromatographic peak.

### Molecular modeling<sup>30</sup>

The binding mode of the compound **14i** and PLK4 was conducted by structure based docking studies, which was carried out by using AutoDock 4.0. The structure of the receptor was taken from PDB (PDB ID: 4JXF). The binding site of the inhibitor was chosen as active site, grid dimensions were 40 × 40 × 40 Å<sup>3</sup>, which were defined by AutoDock tools.

### Acknowledgements

This work was supported by China Postdoctoral Science Foundation (No. 2015M570790, No. 2016T90860). We thank Lihua

Zhou of State Key Laboratory of Biotherapy (Sichuan University) for NMR measurements.
