# Enhancement of the near-infrared emission of Ce<sup>3+</sup>–Yb<sup>3+</sup> co-doped Y<sub>3</sub>Al<sub>5</sub>O<sub>12</sub> phosphors by doping Bi<sup>3+</sup> ions

K. Santhosh Kumar,<sup>a</sup> Chaogang Lou,<sup>a</sup> A. Gowri Manohari,<sup>b</sup> Cao Huihui<sup>a</sup> and Didier Pribat<sup>a</sup>

Ce<sup>3+</sup>–Yb<sup>3+</sup> co-doped Y<sub>3</sub>Al<sub>5</sub>O<sub>12</sub> phosphors are one of most the potential candidates of down-conversion materials for photovoltaic cells. To improve the near-infrared emission from Yb<sup>3+</sup> ions, Bi<sup>3+</sup> ions were introduced into the phosphors. The experimental results showed that the intensity of Yb<sup>3+</sup> emission was greatly enhanced after doping Bi<sup>3+</sup> ions into the phosphors. This may be attributed to an additional pathway via Bi<sup>3+</sup> ions for the energy transfer from Ce<sup>3+</sup> to Yb<sup>3+</sup>. Different from the co-doped phosphors, where the energy of Ce<sup>3+</sup> ions was transferred only to Yb<sup>3+</sup> ions, in Bi<sup>3+</sup>–Ce<sup>3+</sup>–Yb<sup>3+</sup> tri-doped phosphors, the energy of Ce<sup>3+</sup> ions could be transferred not only to Yb<sup>3+</sup> ions but also to Bi<sup>3+</sup> ions. Then, Bi<sup>3+</sup> ions transferred part of the energy to Yb<sup>3+</sup> ions. This enabled Yb<sup>3+</sup> ions to obtain more energy and enhance their near-infrared emission.

## Introduction

Crystalline silicon (c-Si) solar cells have quickly developed over the past few decades because of the huge demand for clean energy.<sup>1,2</sup> One of the factors limiting the conversion efficiency of the solar cells is the spectral mismatch between the solar spectrum and the energy band gap of silicon.<sup>1,3</sup> This results in the problems that the photons with energies lower than the band gap cannot be absorbed, and the higher-energy photons lose the excess of the energy in the cells through thermalization. A possible solution to the latter problem is to cut a higher-energy photon into two or more near-infrared (NIR) photons, which can still be absorbed by the cells.<sup>4</sup>

A down-conversion process is considered to be a promising way to enhance the efficiency of solar cells because it provides the possibility of converting one higher-energy photon into two or more lower-energy photons.<sup>5,6</sup> It has been reported that by this way, the maximum conversion efficiency of the c-Si solar cells could be greatly improved.<sup>4</sup> For this reason, down-conversion materials have attracted significant attention in recent years.<sup>7–10</sup>

Rare earth (RE) phosphors have been considered as one of the potential candidates of down-conversion materials because RE ions have rich energy level structures, which allow efficient spectral conversion.<sup>11</sup> Among RE ions, Yb<sup>3+</sup> ions are desirable due to their high luminescence quantum efficiency and emitted wavelength (950–1050 nm), which is close to the band gap of

Si.<sup>12</sup> To date, a number of studies have been performed on the RE<sup>3+</sup>–Yb<sup>3+</sup> co-doped phosphors, in which RE<sup>3+</sup> ions (RE = Tb, Tm, Pr, Er, Nd, and Ho) were used as sensitizers and Yb<sup>3+</sup> ions were used as activators.<sup>13–17</sup> However, the weak and narrow absorption of these sensitizers prevented them from being applied as photovoltaic down-conversion materials.<sup>18</sup>

On the other hand, some rare earth ions, such as Ce<sup>3+</sup> and Eu<sup>2+</sup>, with broader absorption have also been used as sensitizers in the phosphors.<sup>19–22</sup> Because of the success of Ce<sup>3+</sup>-doped Y<sub>3</sub>Al<sub>5</sub>O<sub>12</sub> (YAG) phosphors in semiconductor lighting, Ce<sup>3+</sup>–Yb<sup>3+</sup> co-doped Y<sub>3</sub>Al<sub>5</sub>O<sub>12</sub> phosphors have naturally been considered as potential down-conversion materials.<sup>19</sup> Although several attempts have been made in this regard, the efficiency of the energy transfer from Ce<sup>3+</sup> to Yb<sup>3+</sup> in the phosphors is still not satisfactory due to the complicated mechanism.<sup>23,24</sup>

In this study, Bi<sup>3+</sup> ions were introduced into Ce<sup>3+</sup>–Yb<sup>3+</sup> co-doped YAG phosphors to improve the energy transfer from Ce<sup>3+</sup> to Yb<sup>3+</sup>. Their influences on the emission of Yb<sup>3+</sup> and the energy transfers between Bi<sup>3+</sup>, Ce<sup>3+</sup>, and Yb<sup>3+</sup> were studied.

## Experimental

Bi<sup>3+</sup>–Ce<sup>3+</sup>–Yb<sup>3+</sup> tri-doped YAG phosphors were prepared by a traditional solid-state reaction method. The powders of Y<sub>2</sub>O<sub>3</sub> (99.99%), Al<sub>2</sub>O<sub>3</sub> (99.99%), Bi<sub>2</sub>O<sub>3</sub> (99%), Ce<sub>2</sub>O<sub>3</sub> (99.99%), and Yb<sub>2</sub>O<sub>3</sub> (99.99%) were stoichiometrically mixed. Then, the mixture was transferred into an alumina crucible and heated at 1600 °C for 6 h in an N<sub>2</sub> + H<sub>2</sub> atmosphere in a chamber furnace. The samples were cooled down to room temperature and were ground again. The excitation and emission spectra of the phosphors were obtained using Ocean Optics MAYA 2000PRO. Fluorescence lifetimes were measured using a FM-4P-TCSPC

spectrofluorometer (Horiba Jobin Yvon). All the measurements were carried out at room temperature.

## Results and discussion

Fig. 1 shows the emission spectra of  $\text{Y}_{3-x-y-z}\text{Al}_5\text{O}_{12} : x\text{Bi}^{3+}, y\text{Ce}^{3+}, z\text{Yb}^{3+}$  ( $x = 0, 0.03; y = 0.01$ ; and  $z = 0.05, 0.1, 0.15, 0.2$ , and  $0.25$ ) phosphors under an excitation of 455 nm. It can be seen that the emissions from  $\text{Ce}^{3+}$  and  $\text{Yb}^{3+}$  vary with the  $\text{Yb}^{3+}$  concentration. When  $\text{Yb}^{3+}$  concentration was low ( $z = 0.05, 0.1$ , and  $0.15$ ), the NIR emission from  $\text{Yb}^{3+}$  ions increased with an increase in the  $\text{Yb}^{3+}$  concentration. This occurred because the energy transferred to  $\text{Yb}^{3+}$  from  $\text{Ce}^{3+}$  increased with the concentration of  $\text{Yb}^{3+}$ . This is also the reason why the emission from  $\text{Ce}^{3+}$  ions decreased with the increasing  $\text{Yb}^{3+}$  concentration. When the  $\text{Yb}^{3+}$  concentration continued to increase to  $z = 0.2$  and  $0.25$ , although the energy from  $\text{Ce}^{3+}$  to  $\text{Yb}^{3+}$  increased, the  $\text{Yb}^{3+}$  emission became weaker due to the concentration quenching effect of  $\text{Yb}^{3+}$ .<sup>25</sup>

The most desirable result, as shown in Fig. 1, is that in the cases of  $x = 0.03, y = 0.01$ , and  $z = 0.05, 0.10$ , and  $0.15$ , the intensity of NIR emission from  $\text{Yb}^{3+}$  ions in  $\text{Bi}^{3+}\text{-Ce}^{3+}\text{-Yb}^{3+}$  tri-doped phosphors was stronger than that in  $\text{Ce}^{3+}\text{-Yb}^{3+}$  co-doped phosphors ( $x = 0, y = 0.01$ , and  $z = 0.1$ ). Fig. 2 shows the

Fig. 1 The emission spectra of different YAG phosphors under the excitation of 455 nm.

Fig. 2 Emission intensities of  $\text{Yb}^{3+}$  at 1027 nm from different YAG phosphors under the excitation of 455 nm.

intensities of the emissions at 1027 nm from the phosphors with different chemical compositions. Although the NIR emission of the tri-doped samples when  $z = 0.2$  and  $0.25$  was weaker than that of the co-doped phosphors due to the concentration quenching effect of  $\text{Yb}^{3+}$ , the stronger emission of the tri-doped phosphors when  $z = 0.05, 0.10$ , and  $0.15$  indicated that the introduction of  $\text{Bi}^{3+}$  ions could improve the emission from  $\text{Yb}^{3+}$  ions.

Because  $\text{Yb}^{3+}$  ions cannot absorb the photons with a wavelength of 455 nm, their emission resulted from the energy transfer inside the phosphors. To explain the curves shown in Fig. 1 and 2, it is necessary to clarify the energy transfers between  $\text{Bi}^{3+}$ ,  $\text{Ce}^{3+}$ , and  $\text{Yb}^{3+}$  ions in the tri-doped phosphors. Fig. 3 shows the luminescence decay curves of  $\text{Ce}^{3+}$  (monitored at 560 nm) in singly  $\text{Ce}^{3+}$ -doped ( $x = 0, y = 0.01$ , and  $z = 0$ ),  $\text{Ce}^{3+}\text{-Yb}^{3+}$  co-doped ( $x = 0, y = 0.01$ , and  $z = 0.1$ ), and  $\text{Bi}^{3+}\text{-Ce}^{3+}\text{-Yb}^{3+}$  tri-doped ( $x = 0.03, y = 0.01$ , and  $z = 0.05, 0.1, 0.15$ , and  $0.2$ ) YAG phosphors under the excitation of 455 nm. Clearly, the emission from  $\text{Ce}^{3+}$  in the tri-doped phosphors decayed faster than that in the  $\text{Ce}^{3+}\text{-Yb}^{3+}$  co-doped phosphors. Because the tri-doped samples have  $\text{Bi}^{3+}$  ions, whereas the co-doped sample does not, the faster decay of the emission from  $\text{Ce}^{3+}$  in the tri-doped phosphors might be attributed to the energy transfer from  $\text{Ce}^{3+}$  ions to  $\text{Bi}^{3+}$  ions.

To understand the energy transfer in detail, the efficiency of the energy transfers from  $\text{Ce}^{3+}$  to other ions was calculated. According to previous studies,<sup>26,27</sup> the energy transfer efficiency  $\eta_{\text{ETE}}$  can be estimated using the following equation:

$$\eta_{\text{ETE}} = 1 - \frac{\tau_{\text{R}}}{\tau_{\text{R0}}} \quad (1)$$

where  $\tau_{\text{R0}}$  is the fluorescence lifetime of the donor (sensitizer) in the absence of acceptors (activators) and  $\tau_{\text{R}}$  is the fluorescence lifetime of the donor in the presence of acceptors. The fluorescence lifetime can be obtained using the following equation:<sup>20,28</sup>

$$\tau = \frac{\int_0^{\infty} tI(t)dt}{\int_0^{\infty} I(t)dt} \quad (2)$$

Fig. 3 The decay curves of  $\text{Ce}^{3+}$  emission at 560 nm for YAG phosphors under an excitation of 455 nm.

where  $I(t)$  represents the luminescence intensity at time  $t$ .

From the decay curves shown in Fig. 3, the fluorescence lifetimes of  $\text{Ce}^{3+}$  were calculated to be 15.3 ns in the tri-doped phosphors ( $x = 0.03$ ,  $y = 0.01$ , and  $z = 0.1$ ), 24.3 ns in  $\text{Ce}^{3+}$ – $\text{Yb}^{3+}$  co-doped phosphors ( $x = 0$ ,  $y = 0.01$ , and  $z = 0.1$ ), and 65.7 ns in the singly  $\text{Ce}^{3+}$ -doped phosphors ( $x = 0$ ,  $y = 0.01$ , and  $z = 0$ ). The energy transfer efficiency calculated from the decay curve of  $\text{Ce}^{3+}$  in the tri-doped phosphors was about 76.78%, whereas the energy transfer efficiency in the co-doped phosphors was 63.02%.

The reasonable explanation for the different energy transfer efficiencies in the two types of phosphors was that in the co-doped phosphors, there was only one pathway for the energy transfer. The energy was transferred from  $\text{Ce}^{3+}$  to  $\text{Yb}^{3+}$ , whereas in the tri-doped phosphors, the energy of  $\text{Ce}^{3+}$  could be transferred *via* two pathways. One pathway was from  $\text{Ce}^{3+}$  to  $\text{Yb}^{3+}$  and the other was from  $\text{Ce}^{3+}$  to  $\text{Bi}^{3+}$  to  $\text{Yb}^{3+}$ .

The evidence for the energy transfer from  $\text{Ce}^{3+}$  to  $\text{Bi}^{3+}$  can be found in Fig. 4, which shows the decay curves of  $\text{Ce}^{3+}$  singly doped and  $\text{Ce}^{3+}$ – $\text{Bi}^{3+}$  co-doped YAG phosphors. Under the excitation of 455 nm, the emission of  $\text{Ce}^{3+}$  in the singly doped phosphors showed nearly a single exponential decay with a fluorescence lifetime of 65.7 ns, whereas in  $\text{Ce}^{3+}$ – $\text{Bi}^{3+}$  co-doped samples, the fluorescence lifetime decreased to 56.3 ns. The calculated energy transfer efficiency was 14.31%. This indicated that the energy transfer from  $\text{Ce}^{3+}$  to  $\text{Bi}^{3+}$  was possible inside the phosphors.

After  $\text{Bi}^{3+}$  ions received energy from  $\text{Ce}^{3+}$ , the energy could be partly transferred to  $\text{Yb}^{3+}$ . To prove this, the  $\text{Bi}^{3+}$  singly doped and  $\text{Bi}^{3+}$ – $\text{Yb}^{3+}$  co-doped YAG phosphors were prepared. The evidence of the energy transfer from  $\text{Bi}^{3+}$  to  $\text{Yb}^{3+}$  can be found in Fig. 5 and 6. From Fig. 5(a), it can be seen that an excitation band is centered at 275 nm due to the transition of  $\text{Bi}^{3+}$ :  $^1\text{S}_0 \rightarrow ^1\text{P}_1$ ,  $^3\text{P}_1$  detected by monitoring at 304 and 460 nm. Moreover, a similar excitation spectrum was also obtained for the transition of  $\text{Yb}^{3+}$ :  $^2\text{F}_{5/2} \rightarrow ^2\text{F}_{7/2}$  at the monitoring wavelength of 1028 nm. The similarity in the shape of both excitation spectra can be considered as a direct evidence for the energy transfer (ET) from  $\text{Bi}^{3+}$  to  $\text{Yb}^{3+}$ . The emission spectra of singly doped  $\text{Bi}^{3+}$

Fig. 4 The decay curves of  $\text{Ce}^{3+}$  emission at 560 nm for  $\text{Ce}^{3+}$  singly doped and  $\text{Ce}^{3+}$ – $\text{Bi}^{3+}$  co-doped YAG phosphors under an excitation of 455 nm.

Fig. 5 (a) Excitation spectra of  $\text{Y}_{2.87}\text{Al}_5\text{O}_{12}:\text{Bi}_{0.03}^{3+}\text{Ce}_{0.1}^{3+}$  monitored at the emission wavelengths of 304 nm, 460 nm, and 1028 nm and (b) emission spectra of  $\text{Bi}^{3+}$  singly doped and  $\text{Bi}^{3+}$ – $\text{Yb}^{3+}$  co-doped YAG phosphors under an excitation wavelength of 275 nm.

Fig. 6 The decay curves of  $\text{Bi}^{3+}$  emission at 304 nm for  $\text{Bi}^{3+}$  singly doped and  $\text{Bi}^{3+}$ – $\text{Yb}^{3+}$  co-doped YAG phosphors under an excitation of 275 nm.

and co-doped  $\text{Bi}^{3+}$ – $\text{Yb}^{3+}$  phosphors under the excitation of 275 nm are shown in Fig. 5(b). The singly doped  $\text{Bi}^{3+}$  spectrum depicts two emission peaks centered at 304 nm and 460 nm. In the co-doped  $\text{Bi}^{3+}$ – $\text{Yb}^{3+}$  samples, apart from the emissions of  $\text{Bi}^{3+}$  ions, a strong NIR emission of  $\text{Yb}^{3+}$  could also be obtained at 1028 nm, which was accompanied by several weak shoulder peaks due to the transitions among different Stark levels of  $^2\text{F}_j$  ( $j = 5/2, 7/2$ ) in  $\text{Yb}^{3+}$ . Because  $\text{Yb}^{3+}$  ions cannot absorb the photons of 275 nm, their NIR emission indicates an energy transfer from  $\text{Bi}^{3+}$  to  $\text{Yb}^{3+}$ .

Fig. 6 shows the decay curves of singly  $\text{Bi}^{3+}$  doped and  $\text{Bi}^{3+}$ – $\text{Yb}^{3+}$  co-doped phosphors under an excitation of 275 nm. The faster decay of  $\text{Bi}^{3+}$  emission in the co-doped samples also proved the energy transfer from  $\text{Bi}^{3+}$  to  $\text{Yb}^{3+}$ . From Fig. 6, the fluorescence lifetime of  $\text{Bi}^{3+}$  was calculated as 768 ns in the singly doped phosphors, decreased to 576 ns after  $\text{Yb}^{3+}$  ions were introduced. The calculated energy transfer efficiency from  $\text{Bi}^{3+}$  to  $\text{Yb}^{3+}$  was 24.95%.

In principle, the amount of the energy transferred from  $\text{Ce}^{3+}$  to  $\text{Yb}^{3+}$  in the tri-doped phosphors should be close to that in

$\text{Ce}^{3+}$ – $\text{Yb}^{3+}$  co-doped phosphors because these two types of phosphors have the same concentrations of  $\text{Ce}^{3+}$  and  $\text{Yb}^{3+}$ .<sup>29</sup> This should result in similar intensities in the NIR emission from  $\text{Yb}^{3+}$ . However, in the tri-doped phosphors, besides transferring energy to  $\text{Yb}^{3+}$ ,  $\text{Ce}^{3+}$  could also transfer energy to  $\text{Bi}^{3+}$ . The energy transferred to  $\text{Bi}^{3+}$  was then partly transferred to  $\text{Yb}^{3+}$ ; thus,  $\text{Yb}^{3+}$  ions obtained more energy in the tri-doped phosphors than in the co-doped phosphors. This is why the NIR emission from  $\text{Yb}^{3+}$  in the tri-doped phosphors was stronger than that in the co-doped phosphors, as shown in Fig. 1.

Based on the abovementioned results, the possible energy transfer processes were analyzed, and the schematic energy level diagram is shown in Fig. 7. In the  $\text{Ce}^{3+}$ – $\text{Bi}^{3+}$ – $\text{Yb}^{3+}$  tri-doped phosphors, the possible energy transfer processes takes place in four ways:  $\text{Ce}^{3+} \rightarrow \text{Yb}^{3+}$ ,  $\text{Ce}^{3+} \rightarrow \text{Bi}^{3+}$ ,  $\text{Bi}^{3+} \rightarrow \text{Yb}^{3+}$ , and  $\text{Ce}^{3+} \rightarrow \text{Bi}^{3+} \rightarrow \text{Yb}^{3+}$ . For the first energy transfer of  $\text{Ce}^{3+} \rightarrow \text{Yb}^{3+}$ , the energy of the  $5d \rightarrow 4f$  transition of  $\text{Ce}^{3+}$  was approximately twice as high as the energy of the  $^2\text{F}_{5/2} \rightarrow ^2\text{F}_{7/2}$  transition of  $\text{Yb}^{3+}$ . The energy of  $\text{Ce}^{3+}$  transferred to  $\text{Yb}^{3+}$  by two possible ways. One way was that one UV/blue photon was converted into two NIR photons by a cooperative energy transfer (CET),<sup>30</sup> other was that the energy transferred from  $\text{Ce}^{3+}$  to  $\text{Yb}^{3+}$  via a charge transfer state (CTS).<sup>24,31,32</sup> To date, both CTS and CET models lack direct experimental evidence and are still in dispute. For the second energy transfer process of  $\text{Ce}^{3+} \rightarrow \text{Bi}^{3+}$ , the mechanism was more complicated. The electrons of the excited  $5d$  state of  $\text{Ce}^{3+}$  ions could transit to the  $^3\text{P}_2$  state of  $\text{Bi}^{3+}$  ions because these two energy levels were close to each other. On the other hand, after  $\text{Bi}^{3+}$  ions obtain the energy, part of electrons of the excited  $^3\text{P}_2$  state of  $\text{Bi}^{3+}$  ions could transit back to  $5d$  state of  $\text{Ce}^{3+}$  ions, and rest of the electrons transited to  $^2\text{F}_{5/2}$  level of  $\text{Yb}^{3+}$  or the ground state  $^1\text{S}_0$  of  $\text{Bi}^{3+}$ . For the third energy transfer of  $\text{Bi}^{3+} \rightarrow \text{Yb}^{3+}$ , the energy level  $^3\text{P}_1$  of  $\text{Bi}^{3+}$  was approximately twice as high as the energy difference between the  $^2\text{F}_{5/2}$  and  $^2\text{F}_{7/2}$  levels of  $\text{Yb}^{3+}$ . The energy of  $\text{Bi}^{3+}$  might directly transfer to nearby  $\text{Yb}^{3+}$  ions via CET.<sup>33</sup> On the basis of the abovementioned ET processes, the fourth energy transfer of  $\text{Ce}^{3+} \rightarrow \text{Bi}^{3+} \rightarrow \text{Yb}^{3+}$  is easy to be understood. At an excitation of 455 nm, after  $\text{Ce}^{3+}$  ions were excited to the  $5d$  state, part of the excited electrons transited to the  $^2\text{F}_{5/2}$  and  $^2\text{F}_{7/2}$  states of  $\text{Ce}^{3+}$ , and part of the excited electrons transited to the  $^3\text{P}$  states of  $\text{Bi}^{3+}$  ions and then  $\text{Bi}^{3+}$  transferred energy to  $\text{Yb}^{3+}$ .

Fig. 7 Schematic energy level diagram of  $\text{Ce}^{3+}$ – $\text{Bi}^{3+}$ – $\text{Yb}^{3+}$  tri-doped  $\text{Y}_3\text{Al}_5\text{O}_{12}$  phosphors.

According to the above mentioned ET processes,  $\text{Bi}^{3+}$  ions, as the new pathway for the energy transfer, played an important role in enhancing the NIR emission of  $\text{Ce}^{3+}$ – $\text{Bi}^{3+}$ – $\text{Yb}^{3+}$  tri-doped  $\text{Y}_3\text{Al}_5\text{O}_{12}$  phosphors.

Note that the enhancement of NIR emission from  $\text{Yb}^{3+}$  by introducing  $\text{Bi}^{3+}$  ions into  $\text{Ce}^{3+}$ – $\text{Yb}^{3+}$  co-doped phosphors does not mean that other ions have similar effects. We attempted to dope  $\text{Tb}^{3+}$  ions into  $\text{Ce}^{3+}$ – $\text{Yb}^{3+}$  co-doped phosphors, but did not observe an improvement in  $\text{Yb}^{3+}$  emission. Therefore, clarifying the mechanism of the energy transfer in the  $\text{Bi}^{3+}$ – $\text{Ce}^{3+}$ – $\text{Yb}^{3+}$  YAG phosphors is important to further improve the NIR emission in future studies.

## Conclusions

The NIR emission from  $\text{Yb}^{3+}$  in  $\text{Ce}^{3+}$ – $\text{Yb}^{3+}$  co-doped  $\text{Y}_3\text{Al}_5\text{O}_{12}$  phosphors under an excitation of 455 nm was improved by introducing  $\text{Bi}^{3+}$  ions. This was because  $\text{Ce}^{3+}$  ions transferred energy to  $\text{Bi}^{3+}$  ions in addition to  $\text{Yb}^{3+}$  ions in  $\text{Bi}^{3+}$ – $\text{Ce}^{3+}$ – $\text{Yb}^{3+}$  tri-doped YAG phosphors. Then, the energy of  $\text{Bi}^{3+}$  ions was partly transferred to  $\text{Yb}^{3+}$  ions. This made  $\text{Yb}^{3+}$  ions obtain more energy in the tri-doped phosphors than in the co-doped phosphors and resulted in more NIR emission.
