# Colloidal synthesis and characterization of single-crystalline Sb<sub>2</sub>Se<sub>3</sub> nanowires†

Yike Liu,<sup>a</sup> Yaqin Tang,<sup>a</sup> Ying Zeng,<sup>a</sup> Xun Luo,<sup>a</sup> Jingyu Ran,<sup>a</sup> Yongmei Luo,<sup>a</sup> Xiangdong Su,<sup>a</sup> Boon K. Ng,<sup>c</sup> Fangyang Liu<sup>\*b</sup> and Liangxing Jiang<sup>\*b</sup>

In the present study, single-crystalline Sb<sub>2</sub>Se<sub>3</sub> nanowires have been synthesized by a hot-injection method. The crystal structure of the prepared Sb<sub>2</sub>Se<sub>3</sub> nanowires has been comprehensively characterized by a series of techniques, namely X-ray diffraction (XRD), Raman spectroscopy, transmission electron microscopy (TEM) as well as selected area electron diffraction (SAED). The mechanism of formation of amorphous phase and nanowires has also been intensively investigated. It is evident that the formation of Sb<sub>2</sub>Se<sub>3</sub> nanowires strongly depends on the reaction temperature. A band gap of 1.06 eV for Sb<sub>2</sub>Se<sub>3</sub> nanowires has been ascertained from UV-vis-NIR measurements. Moreover, coated film consisting of Sb<sub>2</sub>Se<sub>3</sub> nanowires demonstrates a clear photoresponse in photoelectrochemical measurements. This work has conclusively demonstrated that Sb<sub>2</sub>Se<sub>3</sub> nanowires have great potential in solar energy conversion.

## Introduction

Antimony selenide (Sb<sub>2</sub>Se<sub>3</sub>), one of the most important metal selenides, is an intriguing functional material owing to its outstanding applicability spanning the photovoltaic,<sup>1–5</sup> optoelectronic,<sup>6–8</sup> photothermal,<sup>9</sup> and thermoelectric<sup>10</sup> fields. Sb<sub>2</sub>Se<sub>3</sub> has a broad absorption range in the visible spectrum (absorption coefficient > 10<sup>5</sup> cm<sup>−1</sup>) with a suitable band gap of ~1.0 eV, making it an emerging candidate for photovoltaics.<sup>2,11</sup> On top of this, Sb<sub>2</sub>Se<sub>3</sub> is relatively earth-abundant and nontoxic, and is cost-effective yet environmentally friendly.<sup>1,5</sup>

In recent years, the use of nanostructured precursors in the fabrication of thin films for solar cell applications has gained popularity.<sup>12,13</sup> Compared with conventional physical vapor deposition methods, solution-based routes are associated with lower fabrication costs as well as high-quality nanocrystals including nanoparticles, nanowires and nanosheets leading to high power conversion efficiency.<sup>14</sup> Hot-injection is an excellent solution-based route, which can exhibit better control of nanocrystal morphology and size within a short reaction time.<sup>15</sup> This technique has been widely employed for the preparation of numerous monodisperse colloidal nanocrystals.

However, investigations on the synthesis of single-crystalline Sb<sub>2</sub>Se<sub>3</sub> nanowires *via* the hot-injection method have scarcely been reported until recently. In 2009, Deng *et al.* first reported the

synthesis of Sb<sub>2</sub>Se<sub>3–x</sub>S<sub>x</sub> (0 < x < 3) nanotubes *via* a hot-injection method in paraffin liquid,<sup>16</sup> and an extension of this work was published in 2014. Choi and coworkers also studied the synthesis of Sb<sub>2</sub>Se<sub>3</sub> nanowires *via* injection of antimony precursor into hot solvent comprising selenium powder and surfactant.<sup>17</sup> Sb<sub>2</sub>Se<sub>3</sub> nanorods were then prepared using a similar process.<sup>18</sup> However, the reactivity of Se-octadecene suspension has been found to be problematic as it exerted a negative impact on nanocrystal quality.<sup>19,20</sup> Recently, fabrication of ultralong Sb<sub>2</sub>Se<sub>3</sub> nanowires has been successfully accomplished *via* an organometallic synthesis by reacting triphenylantimony(III) with dibenzyldiselenide.<sup>9</sup> The major drawback of this synthesis process, however, is that dibenzyldiselenide is a hazardous, expensive and environmentally harmful Se precursor. Therefore, a facile, environmentally friendly and more effective method for the synthesis of high quality and uniform single-crystalline Sb<sub>2</sub>Se<sub>3</sub> nanowires is highly desired.

Consequently, this work focuses on the synthesis of Sb<sub>2</sub>Se<sub>3</sub> nanowires through a facile and green hot-injection method using oleylamine (OLA). In this process, a solution consisting of Se-dimethylamine borane (DMAB)–OLA was used as a phosphine-free and highly active Se precursor, as reported in our previous works.<sup>21–23</sup> The structure, morphology, composition and absorptivity of the products were comprehensively characterized using different methods. In addition, the photoresponse of Sb<sub>2</sub>Se<sub>3</sub> nanowires was studied using photoelectrochemical measurements and the potential for solar energy conversion is discussed.

## Experimental

Syntheses of Sb<sub>2</sub>Se<sub>3</sub> nanowires were carried out utilizing a hot-injection method *via* a standard air-inert Schlenk line. In

a typical synthesis, the Se powder was completely dissolved in OLA at 110 °C with the assistance of DMAB as a co-solvent, to give a Se-DMAB-OLA solution. The Se-DMAB-OLA solution was then quickly injected into a hot solution containing antimony chloride at 180 °C for 30 min under an Ar atmosphere. Full experimental details can be found in the ESI†

## Results and discussion

Electron microscopy was conducted to characterize the morphology and structural integrity of the nanowires. Fig. 1 shows representative transmission electron microscopy (TEM) images for the  $\text{Sb}_2\text{Se}_3$  nanowires. According to the TEM images (Fig. 1(a) and (b)), each nanowire had a diameter of 40–60 nm with a typical length of several micrometers (additional SEM images can be found in the ESI†). Fig. 1(c) demonstrates that the lattice spacing of  $\text{Sb}_2\text{Se}_3$  nanowire was *ca.* 3.25 and 3.28 Å. This corresponds to the lattice spacing of the (230) and (021) planes, respectively, for  $\text{Sb}_2\text{Se}_3$  with orthorhombic geometry. The SAED pattern, as shown in Fig. 1(d), indicates that  $\text{Sb}_2\text{Se}_3$  nanowires are single-crystalline. All of these results revealed that the structural integrity of  $\text{Sb}_2\text{Se}_3$  nanowires is preferentially oriented along the [001] direction, which is coincident with previous studies on  $\text{Sb}_2\text{Se}_3$  nanowires and nanorods.<sup>7,24–27</sup>

X-ray diffraction (XRD) was used to further ascertain the crystal structure of the  $\text{Sb}_2\text{Se}_3$  nanowires. Fig. 2(a) displays the XRD pattern of the synthesized sample. It can be seen that the obtained sample is composed of an orthorhombic phase  $\text{Sb}_2\text{Se}_3$  (JCPDS 72-1184). Seven major peaks, namely at  $2\theta = 16.911^\circ$ ,  $27.439^\circ$ ,  $28.130^\circ$ ,  $31.127^\circ$ ,  $32.280^\circ$ ,  $34.124^\circ$  and  $35.584^\circ$  corresponding to (120), (230), (211), (221), (301), (240) and (231), respectively, have been fingerprinted. No evidence of other

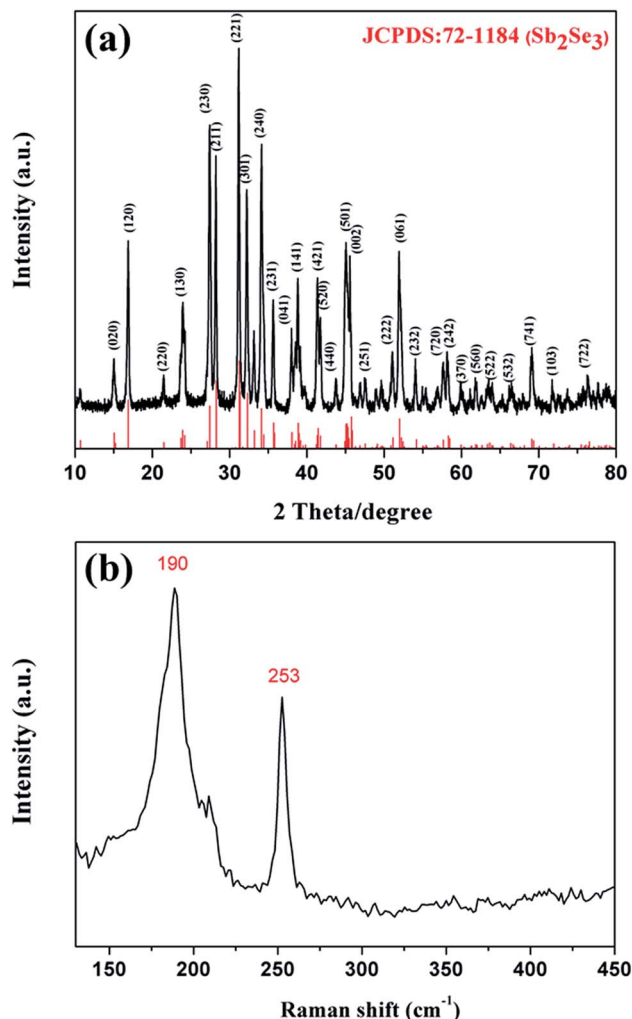

Fig. 2 (a) XRD pattern and (b) Raman spectrum of the as-synthesized  $\text{Sb}_2\text{Se}_3$  nanowires.

Fig. 1 (a and b) Low resolution TEM images of  $\text{Sb}_2\text{Se}_3$  nanowires. (c) High resolution TEM image showing interplanar spacing of 3.25 Å, 3.28 Å and 3.53 Å. (d) SAED pattern indexed to  $\text{Sb}_2\text{Se}_3$ .

impurities such as  $\text{Sb}_2\text{O}_3$ , Sb, *etc.* was found in the respective XRD pattern. The ratio of the compositional elements determined by energy dispersive spectroscopy (EDS) was Sb/Se: 2.00 : 2.88, implying that the composition of the  $\text{Sb}_2\text{Se}_3$  nanowires is close to the stoichiometry of  $\text{Sb}_2\text{Se}_3$  (see the ESI, Fig. S3†). To further validate the phase and purity of the obtained product, Raman spectroscopy and X-ray photoelectron spectroscopy (XPS) have been used. In the Raman spectrum (Fig. 2(b)), the peaks at  $190\text{ cm}^{-1}$  and  $253\text{ cm}^{-1}$  are coincident with previous investigations of  $\text{Sb}_2\text{Se}_3$  nanostructures.<sup>24,28</sup> The results of XPS further demonstrated that both Sb and Se elements are in their expected oxidation states (see the ESI, Fig. S4(a)–(c)†).<sup>24,29</sup> The XRD, Raman and XPS data have demonstrated that the synthesized nanowires are native orthorhombic phase  $\text{Sb}_2\text{Se}_3$ .

To study the crystal growth mechanism of the  $\text{Sb}_2\text{Se}_3$  nanowires, the morphology and structure of the reaction products at different reaction times were monitored by TEM and XRD, as graphed in Fig. S5 and S6 (included in ESI†). During the initial phase (1 min), some amorphous materials were observed. As

the reaction moved forward (2, 4, 8 min), these amorphous materials then clustered into nanowires indicating that the nanowires may nucleate around the amorphous matrix. With a reaction time of just 16 min, the amorphous materials had been depleted to entirely, forming nanowires. The peaks in the corresponding XRD pattern suggest that the proposed product was indeed a pure  $\text{Sb}_2\text{Se}_3$ . From the above-mentioned results, a probable formation route can be conjectured as follows: antimony trichloride was dissolved in oleylamine to form a  $\text{Sb}^{3+}$ -OLA complex initially followed by introduction into the resulting solution. The Se-DMAB-OLA solution was then injected into the hot-injection medium.  $\text{Se}^{2-}$  was the product from the reduction of Se powders by DMAB followed by reaction with OLA to form  $\text{OLA}_m\text{Se}_n$ . The  $\text{Sb}_2\text{Se}_3$  nuclei were then formed *via* homogeneous nucleation. As the reaction moved forward, these  $\text{Sb}_2\text{Se}_3$  crystal nuclei rapidly aggregated into irregular particles where nanowires nucleated *via* the Ostwald ripening process. When the reaction was extended, it resulted in the formation of uniform  $\text{Sb}_2\text{Se}_3$  nanowires. OLA has been successfully employed with a dual role (solvent and surfactant) in the synthesis of  $\text{Sb}_2\text{Se}_3$  nanowires. Previous investigation has demonstrated that OLA can efficiently modify and stabilize the surface of the  $\text{Sb}_2\text{Se}_3$  nanoparticles, resulting in the formation of the  $\text{Sb}_2\text{Se}_3$  nanowires by oriented aggregation.<sup>24</sup> In this reaction, the OLA was adsorbed onto the surface of the  $\text{Sb}_2\text{Se}_3$  nanowires (mainly on  $(hk0)$ ) based on the structural determination, and this further enhanced the anisotropic growth of the  $\text{Sb}_2\text{Se}_3$  nanowires.

The formation of pure  $\text{Sb}_2\text{Se}_3$  nanowires was found to be highly dependent on the reaction temperature. Experiments with various reaction (injection) temperatures have been trialled (see the ESI, Fig. S7†): the products at lower reaction temperature (160 °C) were predominantly in an amorphous phase. When the reaction temperature was below 160 °C, the reaction was slow and incomplete. Higher temperature (200 °C) injection and reaction led to the product containing significant elementary Sb. Kinetically, it has been found that higher temperatures increase the probability for successful nucleation.<sup>30</sup> When the reaction temperature was over 200 °C, elementary Sb that was observed from the experiment could be attributed to the reduction of antimony precursors. OLA has been demonstrated to serve as a surfactant as well as a reductant for the synthesis of various nanocrystal systems at appropriate temperatures.<sup>31,32</sup> It has been proposed that OLA might act as a ligand to form stable complexes with  $\text{Sb}^{3+}$  while heating (high temperature) induces the thermolytic reduction of Sb complexes to elementary Sb in the reaction. Similar phenomena were found in our previous works for the synthesis of  $\text{Cu}_3\text{BiS}_3$  nanocrystals.<sup>33</sup> The synthesis procedure should be carried out at various temperatures ranging from 170 to 190 °C and the reaction can proceed with elevation of the reaction temperature.

Multiple antimony precursors were also examined. Antimony triacetate was found to reproducibly result in pure  $\text{Sb}_2\text{Se}_3$  nanowires. The concentrations of both Sb and Se were also found to be critical in achieving pure samples. It is important to note that when the Sb/Se ratio was 1 : 1.5 at different temperatures, significant  $\text{Sb}_2\text{O}_3$  impurity has been observed in the XRD

Fig. 3 UV-vis-NIR absorption spectrum of the as-synthesized nanowires. Inset shows the absorbance<sup>2</sup> vs. eV for  $\text{Sb}_2\text{Se}_3$  nanowires; the estimated band energy is 1.06 eV.

data (see the ESI, Fig. S8†). The use of excess Se was deemed to be necessary to balance out the cationic precursors in order to avoid side reactions. During a series of trials, the injection quantities of Se were also varied and evaluated where the reaction temperature remained unchanged at 190 °C (see the ESI for details, Fig. S9†). For mole ratios of Sb/Se at 1 : 1.7, pure  $\text{Sb}_2\text{Se}_3$  nanowires were formed.

The absorptivity of the synthesized  $\text{Sb}_2\text{Se}_3$  nanowires was measured using UV-vis-NIR absorbance spectroscopy and is illustrated in Fig. 3. The spectrum presents a slow, monotonic rise in absorption. The band gap of the  $\text{Sb}_2\text{Se}_3$  nanowires has been determined to be 1.06 eV by extrapolating the linearity in the plot of absorbance squared *versus* energy as shown in the inset in Fig. 3. The value is in good agreement with the literature value for bulk  $\text{Sb}_2\text{Se}_3$ .<sup>34</sup> The obtained band gap value for our  $\text{Sb}_2\text{Se}_3$  nanowires is close to the optimal value suited for solar cell application.<sup>35</sup>

In order to further evaluate the applicability of this material for photoelectrical conversion applications, the photo-responsiveness of  $\text{Sb}_2\text{Se}_3$  nanowires was measured in a photo-electrochemical cell (PEC). The  $\text{Sb}_2\text{Se}_3$  nanocrystal-ink was coated directly onto indium tin oxide (ITO) glass substrate (which served as work electrodes) by the drop-casting method, forming a nanocrystalline thin film. This film was mounted onto a traditional three-electrode photoelectrochemical cell with a graphite counter electrode relative to a saturated calomel reference electrode (SCE) containing 0.5 M  $\text{H}_2\text{SO}_4$ . The incident light intensity was 100  $\text{mW cm}^{-2}$ , and a biased voltage of  $-0.4$  V vs. SCE was applied. Fig. 4(a) displays the current density *versus* potential (vs. SCE) plots for the prepared  $\text{Sb}_2\text{Se}_3$  nanowire films utilizing a chopping method (10 s light on, 10 s light off). The photocurrent density increased with a negative shift in cathodic potential, which is a typical characteristic of a p-type semiconductor for a  $\text{Sb}_2\text{Se}_3$  nanowire film. The photocurrents for  $\text{Sb}_2\text{Se}_3$  nanowire films increased significantly with increasing

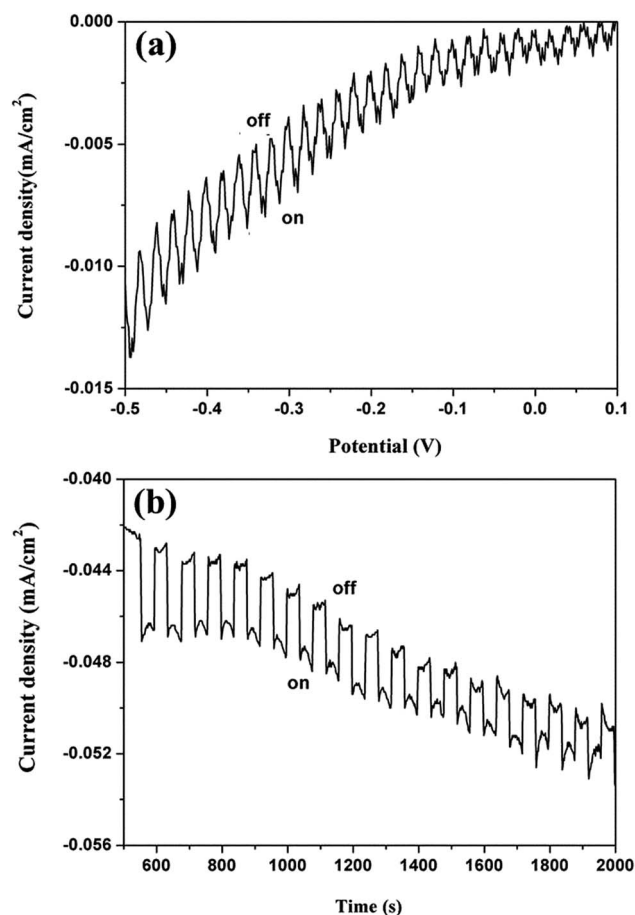

Fig. 4 (a) Photocurrent–potential plot of the  $\text{Sb}_2\text{Se}_3$  films on an ITO substrate in 0.5 M  $\text{H}_2\text{SO}_4$  under  $100 \text{ mW cm}^{-2}$  illumination. (b) The transient photocurrent spectrum at  $-0.4 \text{ V}$  vs. SCE.

negative bias reaching up to  $\sim 6 \mu\text{A cm}^{-2}$  at  $-0.4 \text{ V}$ . The value is almost on par with a previous report where the  $\text{Sb}_2\text{Se}_3$  film was fabricated by an electrochemical deposition process.<sup>8</sup> However, our finding shows a much lower value than that obtained from the reported  $\text{Sb}_2\text{Se}_3$  film formed from annealing treatment and optimization of the coating process.<sup>7</sup> It has been concluded that the annealing treatment can effectively modify the morphology and structural integrity of the  $\text{Sb}_2\text{Se}_3$  nanocrystals and remove the undesirable residual phases.

The transient  $I$ - $V$  spectrum at  $-0.4 \text{ V}$  is depicted in Fig. 4(b). The measured photocurrent values were between 3 and  $5 \mu\text{A cm}^{-2}$ , which remained constant consistently and reproducibly over 18 cycles. This has demonstrated the competent photo-response and photostability of the  $\text{Sb}_2\text{Se}_3$  nanowire film. It also indicates the applicability of  $\text{Sb}_2\text{Se}_3$  nanowires and/or the corresponding thin film in the field of solar energy conversion.

## Conclusions

In this study, a colloidal synthesis of single-crystalline  $\text{Sb}_2\text{Se}_3$  nanowires *via* a hot-injection method has been presented.  $\text{Sb}_2\text{Se}_3$  nanowires with a diameter of 40–60 nm and a typical length of several micrometers have been observed. The

structural integrity of the synthesized  $\text{Sb}_2\text{Se}_3$  nanowires has been evaluated by a number of methods including HRTEM, SAED, XRD and Raman spectroscopy. The results of EDS have confirmed the composition of the  $\text{Sb}_2\text{Se}_3$  nanowires in the sample. A probable formation route has been proposed from the evolution of the morphologies and phases. The reaction temperature has also been found to play a crucial role in determining the phase of the synthesized nanocrystals. The use of antimony triacetate as precursor has also been observed to be instrumental in yielding phase pure  $\text{Sb}_2\text{Se}_3$  nanowires at an appropriate ratio ( $\text{Sb}/\text{Se} = 1 : 1.7$ ) and at  $190^\circ\text{C}$ . The band gap of  $1.06 \text{ eV}$  for  $\text{Sb}_2\text{Se}_3$  nanowires has been determined by UV-vis-NIR data. The PEC tests have also demonstrated that  $\text{Sb}_2\text{Se}_3$  nanowire films have a good photoresponse in the range 3 to  $5 \mu\text{A cm}^{-2}$  without any optimization. Our work has conclusively demonstrated that the synthesized  $\text{Sb}_2\text{Se}_3$  nanowires have great potential in solar energy conversion.
