Synthesis and characterisation of push–pull flavin dyes with efficient second harmonic generation (SHG) properties†

Nabeel Mohammed,‡[a] Alan A. Wiles, [iD] ‡[a] Michael Belsley, [iD] ‡[b] Sara S. M. Fernandes,[c] Michele Cariello,[a] Vincent M. Rotello, [iD] [d] M. Manuela M. Raposo [iD] *[c] and Graeme Cooke [iD] *[a]

Organic compounds displaying second-order non-linear optical properties are key materials for optoelectronics. Here, three push–pull flavin derivates (**FLA-A–C**) have been synthesised and their optical, redox and second harmonic generation (SHG) properties have been investigated. In particular, we describe the role differing electron donor units (*N,N*-dimethylaniline-, *N,N*-diphenylaniline- and ferrocenyl-) attached through the C(8) position of the flavin unit have on the optical and redox properties of the latter. Hyper-Rayleigh scattering in dioxane solutions using a fundamental wavelength of 1064 nm was employed to evaluate their second-order nonlinear optical properties. Our experiments have indicated that their first hyperpolarisabilities (β) are influenced by the electronic nature and strength of the donor groups. *N,N*-dimethylaniline-functionalised derivative **FLA-A**, exhibited the largest first hyperpolarisability ($\beta = 9550 \times 10^{-30}$ esu, using the T convention) and high decomposition temperature ($T_d = 312$ °C), thus indicating its potential application as a useful material for incorporation into non-linear optical devices.

Introduction

Nonlinear optical (NLO) materials represent one of the principal branches of optoelectronics.[1] Applications of NLO materials encompass a range of scientific sub-disciplines including medicine (*e.g.* second harmonic generation (SHG)-imaging, high-resolution optical microscopy for biological imaging) and materials science (*e.g.* frequency conversion of lasers, waveguides and electro-optic modulators, optical transistors, fibres and lenses).[2]

Organic NLO chromophores possess several advantages over their inorganic brethren including convenient synthesis, tunability, straightforward processability, ultrafast response times, lower dielectric constants and enhanced NLO responses.[3] Accordingly, during the last four decades, extensive progress has been made in the improvement of the SHG properties of organic donor–acceptor π-conjugated systems.[4,5]

Organic push–pull NLO chromophores are promising materials, and typically comprise of a strong electron donor (D) (*e.g.* arylamino groups) and strong electron acceptor (A) group (*e.g.* cyano, nitro, di- or tricyanovinyl) linked through a π-bridge (aromatic or heterocyclic) (D–π–A). This D–π–A arrangement promotes efficient intramolecular charge-transfer (ICT) between the D and A groups and generates dipolar push–pull systems possessing an intense, low-energy CT absorption, and the propensity to display strong molecular SHG. The NLO response correlates strongly with the strength of the attached D and A groups as well as the electronic nature and length of the π-conjugated spacer.[3]

Amines (NR₂), such as 4-*N,N*-dimethylaniline- or 4-*N,N*-diphenylaniline-, are commonly used donor groups in NLO chromophores. The latter moieties tend to have a lower electron donating ability due to the partial delocalisation of the nitrogen nonbonding lone pair to the conjugated phenyl units that are usually organised in a nonplanar fashion.[5] On the other hand, *N,N*-diarylaniline moieties usually impart significantly higher thermo- and photostabilities compared to their *N,N*-dialkylaniline analogues. Consequently, chromophores featuring *N,N*-dialkylaniline donor groups tend to show much higher nonlinearities compared to their *N,N*-diarylaniline brethren, although they generally have much lower thermostabilities.[6] Organometallic[7] groups such as ferrocene have also been utilised as D moieties in NLO chromophores.[8] More recently, electron-rich (*e.g.* thiophene and pyrrole) and electron-poor (*e.g.* azoles and diazines) five-membered heterocycles have also been

‡ These authors contributed equally.

used as efficient "non-conventional" electron donor or acceptor moieties, respectively, due to their auxiliary D–A heterocycle effect.[9]

Flavins are electron deficient heterocycles and are important cofactors in a range of flavoenzymes.[10] Synthetic flavin derivatives due to their convenient synthesis, photostability and tunable optical and redox properties have found application in a diverse range of areas including: supramolecular chemistry[11] and photonics such as solvatochromic probes[12] and photon-induced energy and charge transfer systems.[13] However, their application as A units in NLO materials has not been widely reported. For example, Stanley and co-workers have reported that a push–pull flavin derivative displayed a hyperpolarisability (β_0) of 720 × 10^{-30} esu, estimated with the aid of Stark spectroscopy.[14]

Here we report the synthesis and characterisation of three flavin-based dyes **FLA-A–C** featuring *N,N*-dimethylaniline-, *N,N*-diphenylaniline- and ferrocenyl-units attached through the C(8) position of the flavin unit to ensure good electronic communication between the differing D units and the flavin A moiety.[15] **FLA-C** features an acetylene linker unit as these moieties have been shown to increase planarity and charge-transfer in D–A push–pull systems[5b] which in turn increases SHG efficiency.[16] We have investigated their optical and redox properties and have determined their molecular first hyperpolarisabilities (β) using the hyper-Rayleigh scattering (HRS) method which has revealed that these push–pull systems display efficient SHG properties.

Results and discussion

Synthesis

The three push–pull flavins (**FLA-A–C**) have been synthesised from 5-chloro-2-nitroaniline **1** through a simple 4-step route in moderate to high yields (Scheme 1). Firstly, compound **1** was acylated to give compound **2** in high yield. The differing donor moieties were then added to this building block using either Suzuki (compounds **3a** and **3b**) or Sonogashira (compound **3c**) coupling methodologies. Simultaneous reduction of both the carbonyl- and nitro-moieties with LiAlH$_4$ gave compounds **4a–c**. Finally, formation of the flavin moiety was achieved through condensation of **4a–c** with alloxan monohydrate to give the flavin-based dyes **FLA-A–C**.

Optical properties

The UV-vis spectra of the three flavin dyes were recorded to determine their optical properties and solvatochromic behaviour, as the latter has been shown to have strong correlation to the ability of compounds to display SHG properties.[17] Fig. 1 shows that the three dyes have a broad absorption in the visible region. **FLA-A** and **FLA-B** show the highest absorbance values at 536 nm (3066 L mol^{-1} cm^{-1}) and 517 nm (4009 L mol^{-1} cm^{-1}) nm, respectively. On the other hand, **FLA-C** shows a highest absorbance at 454 nm (2657 L mol^{-1} cm^{-1}) nm and a weaker but longer wavelength absorption at 566 nm (873 L mol^{-1} cm^{-1}), which we assign as π-LUMO and metal-LUMO bands, respectively.[18] Investigation of the influence solvent polarity has on the absorbance of dyes **FLA-A–C** (Fig. 2) has revealed that significant solvatochromic behaviour exists for this series of dyes. In accordance with previously reported data for a related push–pull flavin derivative, the λ_{max} values for **FLA-A–B** did not display a linear correlation with solvent polarity (dielectric constant or $E_T(30)$), suggesting that solute–solvent interactions are occuring.[12] Interestingly, the position of the metal-LUMO absorption bands of **FLA-C** are in broad correlation with the dielectric constants for the different solvents.

Fig. 2   Normalised UV-vis absorption spectra of **FLA-A–C** recorded in four different solvents (1×10^{-4} M).

Electrochemistry

The redox properties of the dyes have been investigated using cyclic voltammetry (see ESI, Fig. S4†). Each dye displays a pseudo-reversible oxidation and reduction wave. The differing donor abilities of the D units play a predictable effect on the electron affinities of the dyes (**FLA-A** −3.55 eV, **FLA-B** −3.88 eV, **FLA-C** −3.76 eV),[15] whereas the ionisation potentials of these moieties show a more marked variation (**FLA-A** −5.32 eV, **FLA-B** −5.49 eV, **FLA-C** −4.99 eV) in line with their structurally and electronically differing D moieties.

NLO properties

The molecular first hyperpolarisabilities β of flavin derivatives **FLA-A–C** were measured by the hyper-Rayleigh scattering (HRS) method[19] at a fundamental wavelength of 1064 nm and the data are summarised in Table 1. It is clear that the electronic donor ability of the moieties attached at the position C(8) of the flavin derivative for compounds **FLA-A–C** modulates the red-shifted absorption maxima and nonlinearities as anticipated from the donor strengths of the substituents (ferrocenyl- < 4-*N*,*N*-diphenylaniline- < 4-*N*,*N*-dimethylaniline-). These results are not unexpected bearing in mind the Hammett σ_p constants of *N*,*N*-dimethylaniline ($\sigma_p = -0.83$), *N*,*N*-diphenylaniline ($\sigma_p = -0.56$) and ferrocenyl ($\sigma_p = -0.18$), donor groups[20] as well as data provided in several earlier studies.[6] Therefore, 4-*N*,*N*-dimethylaniline, being the strongest electron-donor group, gives rise to a higher β value for compound **FLA-A**.[21] On the other hand, the ferrocenyl derivative **FLA-C** exhibits the lowest hyperpolarisability ($\beta = 355 \times 10^{-30}$ esu) compared to **FLA-A** and **B** ($\beta = 9550$ and 8660×10^{-30} esu, respectively).

Thermal stabilities

In order to be readily incorporated into efficient optoelectronic devices, organic NLO-phores should exhibit large molecular quadratic hyperpolarisability, good optical transparency and excellent thermal and chemical stabilities. Derivatives that feature alkyl- and aryl-amine moieties as their donor units have been shown to possess these important properties.[5a,6] The thermal stability of chromophores **FLA-A–C** was studied by thermogravimetric analysis (TGA) and by differential scanning calorimetry (DSC) (see Fig. S1–S3, ESI†). **FLA-A–C** exhibit high decomposition temperatures of 312, 329 and 319 °C respectively. Comparison of the thermal stability of *N*,*N*-dimethylaniline derivative **FLA-A** with flavin **FLA-B** shows that the *N*,*N*-diphenylaniline-substitution results in an enhanced thermal stability which is in agreement with previous findings.[5a,6]

Theoretical calculations

To further our understanding of the properties of these dyes and establish a comparative computational basis for this series, density functional theory (DFT) calculations were undertaken. The HOMO and LUMO maps of **FLA-A–C** were computed in

a polarized solvent continuum of 1,4-dioxane (Fig. 3) and show diffuse and overlapping HOMO and LUMO densities. **FLA-A** shows the most extensive overlap of HOMO/LUMO densities which is consistent with good CT between the strongest *N,N*-dimethylaniline donor and flavin moieties. The estimated dipole moments for these molecules range between 13 and 17 Debye (in 1,4-dioxane), and follows the same trend as the experimentally determined hyperpolarisabilities (Tables 1 and 2). Interestingly, the magnitude of the calculated hyperpolarisabilities have little correlation with the experimentally determined values for **FLA-A** and **B** in this solvent.

The geometry of each of the dyes were also optimised under differing solvent continua and the dipole moments were calculated. For all dyes the largest calculated dipole moment was obtained in DMSO, with 1,4-dioxane providing the lowest value (Tables 3 and S2, ESI†). Interestingly, for each solvent studied the magnitude of the calculated dipole moment follows the same general trend as the experimentally determined hyperpolarizability values of the dyes. Furthermore, solvent polarity also seems to affect the magnitude of the HOMO more than the LUMO of these compounds (Table S2, ESI†). Bearing in mind the important relationship between solvatochromism, polarizability and the extrapolation to hyperpolarizability values in second order NLO materials,[17] the data suggest that for these systems DFT predictions of dipole moment (and its solvent dependency) may offer a better yardstick for designing new analogues with large hyperpolarisability values than their calculated hyperpolarisabilities.

Experimental

General methods

All reactions were undertaken under inert atmosphere. Solvents were purified using a Pure Solv™ solvent purifier system. Reagents were purchased from Sigma Aldrich, and were used without further purification. NMR spectra were obtained with either a Bruker AVIII 400 MHz or a Bruker AVIII 500 MHz spectrometer (relative to TMS). UV-vis spectra were recorded on a Perkin Elmer Lamda 25 instrument. Optical band gaps ($E_{G,OPT}$) were estimated using the onset of the longest wavelength absorption (λ) using $E_{G,OPT}$ (eV) = (1240/λ (nm)).

Synthesis

Compound 2. Isobutyryl chloride (1.84 mL, 17.4 mmol) and triethylamine (2.43 mL, 17.4 mmol) were added drop-wise to a solution of 5-chloro-2-nitroaniline **1** (2.00 g, 11.6 mmol) and 4-(dimethylamino)pyridine (0.140 g, 1.74 mmol) dissolved in THF (100 mL). The mixture was stirred overnight at reflux, and the solvents were then removed under reduced pressure. The crude product was then purified by flash chromatography (petroleum ether/ethyl acetate; 95 : 5) and then recrystallised from hot ethanol to yield title compound **2** as yellow needles (2.69 g, 95%). Mp 91–92 °C; δ_H (500 MHz, CDCl$_3$, TMS) 10.56 (1H, s), 8.96 (1H, d, *J* 2.3), 8.18 (1H, d, *J* 9.0), 7.13 (1H, dd, *J* 9.0, 2.3), 2.66 (1H, sept, *J* 6.9), 1.31 (6H, d, *J* 6.9); δ_C (125 MHz, CDCl$_3$, TMS) 176.3, 143.0, 136.3, 134.5, 127.1, 123.4, 121.9, 37.8, 19.4; HRMS (EI$^+$, *m/z*): [M]$^+$ found, 242.0455; calc. for (C$_{10}$H$_{11}$ClN$_2$O$_3^+$), 242.0458.

Compound 3a. Compound **2** (1.00 g, 4.13 mmol), 4-(dimethylamino) phenylboronic acid (1.36 g, 8.26 mmol), NaCl (0.425 g, 4.13 mmol) and K$_2$CO$_3$ (2.28 g, 16.5 mmol) were dissolved in 1,4-dioxane (35 mL) and the solution was degassed for 30 minutes with N$_2$. PdCl$_2$(PPh$_3$)$_2$ (68.3 mg, 83.0 μmol) was added and the solution was left to stir at reflux. After 24 hours the mixture was allowed to cool to room temperature, poured into water (200 mL) and extracted with Et$_2$O (4 × 200 mL). The

General procedure for the synthesis of compounds FLA-A–C. To a solution of **3a–c** in dry THF (7 mL mmol^{-1}) $LiAlH_4$ (10 eq.) was added portion-wise. The reaction mixture was stirred overnight at room temperature. The mixture was then quenched by the addition of water and further addition of 10% aqueous NaOH. The resulting precipitate was filtered off and washed thoroughly with Et_2O. The combined organics were dried over $MgSO_4$ and filtered. The solvent was then removed under reduced pressure to give **4a–c** as a crude product, which was used without further purification. Crude **4a–c**, alloxan

monohydrate (1 eq.) and B_2O_3 (1.5 eq.) were dissolved in glacial acetic acid (2 mL mmol^{-1}) and stirred overnight at room temperature. The solvent was then removed under reduced pressure and the crude product was purified by flash chromatography affording **FLA-A–C**:

FLA-A

Flash column chromatography (DCM/acetone; 90 : 10) afforded **FLA-A** as a dark purple red solid (0.195 g, 38%), from **3a** (0.408 g, 1.00 mmol). Mp > 300 °C; δ_H (400 MHz, $CDCl_3$, TMS) 8.40 (1H, s), 8.26 (1H, d, J 8.7), 7.86 (1H, dd, J 8.7, 1.8), 7.68 (1H, d, J 1.8), 7.66–7.62 (2H, m), 6.86–6.82 (2H, m), 4.70 (2H, bs), 3.09 (6H, s) 2.51(1H, sept, J 6.7), 1.09 (6H, d, J 6.7); δ_C (100 MHz, $CDCl_3$, TMS) 159.9, 155.3, 151.7, 151.5, 149.4, 135.2, 135.1, 134.1, 133.8, 128.7, 125.5, 125.5, 112.8, 111.1, 51.4, 40.3, 27.8, 20.3; HRMS (NSI^+, m/z): $[M + H]^+$ found, 390.1922; calc. for ($C_{22}H_{24}N_5O_2^+$), 390.1925.

FLA-B

Flash column chromatography (DCM/acetone; 90 : 10) afforded **FLA-B** as a dark purple solid (0.132 g, 42%), from **3b** (0.275 g, 0.610 mmol). Mp > 300 °C; δ_H (400 MHz, $CDCl_3$, TMS) 8.37 (1H, s), 8.31 (1H, d, J 8.6), 7.85 (1H, dd, J 8.6, 1.7), 7.71 (1H, s), 7.58–7.54 (2H, m), 7.36–7.31 (4H, m), 7.20–7.12 (8H, m) 4.70 (2H, bs), 2.51 (1H, sept, J 6.7), 1.09 (6H, d, J 6.7); δ_C (100 MHz, $CDCl_3$, TMS) 159.6, 155.1, 151.5, 150.0, 148.7, 146.9, 136.0, 135.3, 133.9, 130.8, 129.8, 128.9, 128.5, 125.8, 125.7, 124.5, 122.2, 112.3, 51.5, 27.8, 20.3; HRMS (NSI^+, m/z): $[M + H]^+$ found, 514.2249; calc. for ($C_{32}H_{28}N_5O_2^+$), 514.2238.

FLA-C

Flash column chromatography (Et_2O/EtOAc; 4 : 1) afforded **FLA-C** as a green solid (0.268 g, 34%), from **3c** (0.683 g, 1.65 mmol). Mp > 300 °C; δ_H (500 MHz, $CDCl_3$, TMS) 8.50 (1H, s), 8.22 (1H, d, J 8.5), 7.65 (1H, dd, J 8.5, 1.4), 7.62 (1H, d, J 1.4), 4.65 (2H, bs), 4.62 (2H, t, J 1.9), 4.40 (2H, t, J 1.9), 4.30 (5H, s), 2.49 (1H, sept, J 6.9), 1.09 (6H, d, J 6.9); δ_C (125 MHz, $CDCl_3$, TMS) 170.2, 154.9; 151.5, 135.2, 133.6, 133.4, 132.6, 129.9, 117.4, 113.2, 98.8, 72.3, 70.4, 70.3, 63.1, 51.5, 31.1, 27.7, 20.2; HRMS (FAB^+, m/z): $[M + H]^+$ found, 479.1176; calc. for ($C_{26}H_{23}N_4{}^{56}FeO_2^+$), 479.1171.

Nonlinear optical measurements using the hyper-Rayleigh scattering (HRS) method

Hyper-Rayleigh scattering (HRS) was used to measure the angle-averaged first hyperpolarisability β response of the molecules studied. The experimental set-up for hyper-Rayleigh measurements has previously been described in detail.[19b] A Q-switched Nd:YAG laser operating at a 10 Hz repetition rate with approximately 10 mJ of energy per pulse and a pulse duration (FWHM) close to 12 ns is used to excite hyper-Rayleigh scattering with an incident wavelength of 1064 nm. The hyper-Rayleigh signal was normalized at each pulse by using a small fraction of the laser pulse to generate a second harmonic signal from a KDP crystal to compensate for fluctuations in the temporal profile of the laser pulses due to longitudinal mode beating. Dioxane was

used as a solvent, and the β values were calibrated using a reference solution of p-nitroaniline (pNA)[23] also dissolved in dioxane at a concentration of 1×10^{-2} mol dm^{-3} (external reference method). The hyperpolarisability of pNA dissolved in dioxane is known from EFISH measurements carried out at the same fundamental wavelength. We have chosen to report our values using the so-called T (Taylor expansion) convention[23b] in which the β_{333} of pNA in dioxane at 1064 nm is 40×10^{-30} esu. This value includes a correction factor of 1.88 that accounts for the most recent measurement of the CCl_4 hyper-Rayleigh scattering signal which was used as a reference.[24]

All solutions were filtered (0.2 µm porosity) to avoid spurious signals from suspended impurities. The small hyper Rayleigh signal that arises from dioxane was taken into account. We took particular care to avoid reporting artificially high hyperpolarisabilities due to a possible contamination of the hyper-Rayleigh signal by molecular fluorescence near 532 nm. Measurements were carried out using two different interference filters with different transmission pass bands centred near the second harmonic at 532 nm allowing us to estimate and correct for any fluorescence emitted near 532 nm.

TGA/DSC

Thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) were performed using a TA Instruments SDT Q-600 series thermal analyser. Gas flow was 100 mL min^{-1}. The DSC curves show exotherms as up and endotherms as down.

Theoretical calculations

Gaussian 09 (ref. 25) was used to estimate solvent dependence and hyperpolarisability factors of the chromophores. The geometry of each dye was initially obtained semi-empirically (PM6). These geometries were then re-optimised at DFT level using the hybrid B3LYP level by employing the 6-31+G** basis set using polarizable continuum model (keyword: scrf = solvent). Frequency calculations were performed to ensure the absence of negative frequencies. Hyperpolarisability factors were estimated using an incident wavelength of 1064 nm (keywords: freq = raman, cphf = rdfreq, polar) and with a polarized solvent continuum using dioxane as the solvent (Table 2).[26]

Conclusions

In conclusion, flavins **FLA-A–C** were readily synthesised from 5-chloro-2-nitroaniline using a simple 4-step synthetic route in moderate to high yields. Evaluation of the first hyperpolarisabilities of **FLA-A–C** using the hyper-Rayleigh scattering technique showed that derivatives **FLA-A** and **FLA-B** bearing stronger donor groups exhibit the higher hyperpolarisabilities ($\beta = 8660$–9550×10^{-30} esu) and higher thermal stabilities thereby indicating their potential future application in NLO devices. The convenient synthesis, good thermal stability and efficient SHG properties of this class of flavin derivatives suggest that related molecules may prove to be interesting candidates for further development. Moreover, the well-documented ability to accurately predict the physical properties of flavins using linear free energy relationships and, as we have shown here DFT calculations, will help ensure that push–pull flavin derivatives of this type, once embedded into acentric structures,[27] will become an important class of NLO materials with predictable properties.
