Effects of oxygen-deficiency on crystal structure, dielectric and ferroelectric properties in $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ with tungsten bronze structure

Bao Li Deng, Xiao Li Zhu, [iD] * Xiao Qiang Liu and Xiang Ming Chen [iD]

Oxygen-deficient tungsten bronze ceramics with general formula $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ ($x = 0, 0.1, 0.25$) are prepared. The effects of oxygen deficiency on the crystal structure, dielectric and ferroelectric properties are investigated. With increasing oxygen deficiency, the crystal structure becomes less stable and the lattice shrinks, while the ferroelectricity is weakened, and the low temperature relaxation enhanced. Commensurate superlattices observed in $Sr_5SmTi_3Nb_7O_{30}$, corresponding to the onset of the ferroelectric transition as reported previously. In compositions with $x = 0.1$ and 0.25, two factors that A-site cross occupancies and disturbance of oxygen vacancies on the ferroelectric order are noticed and related to the change from ferroelectric behavior to diffuse one. Three orders of incommensurate superlattice reflections are observed in $x = 0.1$ and 0.25 compositions. The first-order incommensurate superlattice reflections appear at positions ($h + 1/4 - \delta$, $k + 1/4 - \delta$, $l + 1/2$), reflecting the common feature in tungsten bronzes with relaxor or diffuse ferroelectric nature. The second-order incommensurate superlattice reflections are observed on the ($00l$) ($l = 0, 1, 2, 3, \ldots$) planes around the ($h + 1/2, k + 1/2, l$) positions, while the third-order incommensurate superlattice reflections are observed on the ($00l$) ($l = 1/2, 3/2, \ldots$) planes, by the side of the first-order ones. The appearance of higher-order is believed to reduce the high structural energy induced by the oxygen deficiency.

1. Introduction

The tungsten bronze structure is composed of ten distorted octahedra sharing corners in such a way that three different interstices (2 tetragonal A1, 4 pentagonal A2, and 4 triangle C) are available for cation occupancy in the general formula $(A1)_2(A2)_4(C)_4(B1)_2(B2)_8O_{30}$, which can be obtained from the perovskite structure by rotation of the BO_6 octahedra.[1,2] The chemical composition of tungsten bronzes is very flexible and according to the occupation of the interstices, three types of tungsten bronzes can be defined, such as full-filled (all interstice sites full, exp. $K_3Li_2Nb_5O_{15}$), filled (C site empty, $Ba_2NaNb_5O_{15}$) and un-filled (A site partially occupied and C site empty, $(Sr_xBa_{1-x})Nb_2O_6$) tungsten bronzes. The two kinds of octahedral B sites can by occupied by the same or different cations, like Ti, Fe, Nb, Ta, *etc.*

In recent years, a number of Pb-free ferroelectrics have been determined in tetragonal filled tungsten bronze family of $M_{6-p}R_pTi_{2+p}Nb_{8-p}O_{30}$ ($p = 1, 2$; M = Ba or Sr; R = rare earth).[3–15] In these materials, a ferroelectric transition followed by up to three low-temperature dielectric relaxations are generally

detected with decreasing temperature. Zhu *et al.* reported the ferroelectric transition changes from the normal one to relaxor through diffuse one with decreasing the radius difference between A1- and A2-site ions, Δr.[3] A crystal-chemical model is proposed recently to explore the composition and local structure influence on the relaxor or ferroelectric behavior.[4] The model considers two competing driving forces: large average A-site cation size extends the BO_6 octahedra which enhances polarizability, while low A1 tolerance factor favors modulated tilt pattern of commensurate superstructure and is always associated with normal ferroelectric behavior.

Besides the modulation of positive ions, creation of oxygen vacancies is also an effective way to manipulate the properties of oxides, and oxygen deficiency has been drawing considerable attention in many perovskite oxides.[16–24] Oxygen vacancies can be created by doping or atmospheric reduction.[23,24] According to the authors' experience, for tungsten bronzes $M_{6-p}R_pTi_{2+p}Nb_{8-p}O_{30}$, O_2 or N_2 atmosphere annealing has no obvious effect on the dielectric and ferroelectric properties. This might be one possible reason why the effects of oxygen vacancies in tungsten bronzes have rarely been studied. Recently, effects of oxygen vacancies on the electrical properties in filled tungsten bronze $Ba_4Nd_2Fe_2Nb_8O_{30}$ have been reported.[25] The sensitivity of oxygen vacancies in $Ba_4Nd_2Fe_2Nb_8O_{30}$ to O_2 or N_2 atmosphere

Laboratory of Dielectric Materials, Department of Materials Science and Engineering, Zhejiang University, Hangzhou 310027, China. E-mail: xiaolizi0618@zju.edu.cn

annealing is attributed to the B-site Fe cations with variable valance. For the titanium niobate systems, in order to create oxygen vacancies, a new family of tungsten bronze ceramics $Ba_4Nd_2Ti_{4+2x}Nb_{6-2x}O_{30-x}$ has been synthesized and investigated.[26] With increasing x, the dielectric properties shows a transition from classic ferroelectric behavior with $x = 0$ to a relaxor-like behavior with $x = 1$, reflecting the disturbance of oxygen vacancies on the ferroelectric order. These researches suggest the possibility and significance for studying the effects of oxygen vacancies in tungsten bronzes.

In the present work, chosen Sr-based filled tungsten bronze $Sr_5SmTi_3Nb_7O_{30}$ as the ferroelectric endpoint, oxygen deficient tungsten bronze ceramics $Sr_5Sm_1Ti_{3+2x}Nb_{7-2x}O_{30-x}$ ($x = 0$, 0.1, 0.25) has been prepared, and the crystal structure, dielectric and ferroelectric properties are studied.

2.   Experimental procedure

$Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ ($x = 0$, 0.1, 0.25) ceramics were prepared by a standard solid-state reaction, using reagent grade $SrCO_3$ (99.95%), Sm_2O_3 (99.99%), TiO_2 (99.9%), and Nb_2O_5 (99.99%) powders as the raw materials. The weighed raw materials were mixed by ball milling with zirconia media in deionized water for 24 h. Because of the hydration of Sm_2O_3, it was additionally preheated at 900 °C for 30 minutes before weighing. The three mixtures were calcined in high-purity alumina crucibles at 1300 °C in air for 3 h followed by a second grinding to reach a homogeneous granulometric distribution. Adding with organic binders (8 wt% polyvinyl alcohol), the reground powders were pressed into cylindrical compacts of around 12 mm in diameter and around 1.2 mm in thickness under the pressure of about 98 MPa. The disks were sintered at 1250–1350 °C in air for 3 h to find the best sintering condition for the present ceramics. After sintering, the disks were cooled to 1000 °C at a rate of 2 °C min and further cooled inside the furnace.

The crystalline phase constitution was identified using powder X-ray diffraction (XRD, LabX XRD-6000, SHIMADZU Co., Japan) analysis with Cu Kα radiation. The bulk density of the ceramics was calculated by measuring its mass and diameter. The microstructure of the polished and thermally etched surfaces of the sintered disks was characterized using scanning electron microscopy (SEM, SIRION-100, FEI, Netherlands). Thermal etching was conducted at 1100 °C for 20 min. The XRD data for Rietveld analysis was collected over the 2θ range of 8° to 130° with steps of 0.02° and a count time of 2 s (D/max 3B, Rigaku Co., Tokyo, Japan). The Rietveld structure calculation was carried out using the FULLPROF program. The bulks were thinned around several micrometers mechanically and then polished by ion beam for transmission electron microscopy (TEM) observation. Selected area electron diffractions (SAED) were carried out using a TEM (Tecnai G2 F20 S-TWIN, FEI Co., Hillsboro, USA). Dielectric properties in the range of 173 K to 573 K were measured with a broadband dielectric spectrometer (Turnkey Concept 50, Novocontrol Technologies., Hundsangen, Germany) over a frequency range of 1 Hz to 5 MHz. $P–E$ hysteresis loops are evaluated at room temperature 1 Hz by

a Precision Materials Analyzer (RT Premier II, Radiant Technologies, Inc., NM, USA). The applied electric field increased from 10 kV cm^{-1} to 100 kV cm^{-1}.

3.   Results and discussion

Dense $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ ($x = 0$, 0.1 and 0.25) ceramics with relative density above 95% are obtained. The relative density of the present ceramics decreases with increasing x value, which is due to more oxygen vacancies. The SEM images are shown in Fig. 1, indicating columnar grains for all compositions.

Fig. 2 shows the X-ray diffraction patterns for $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ ($x = 0$, 0.1 and 0.25) ceramics. Tetragonal tungsten bronze structure with space group $P4bm$ is determined by indexing the XRD peaks according to the JCPDS (Joint Committee for Powder Diffraction Standards) card no. 54-0777. Very small amount of secondary phase (cubic $SrTiO_3$ with space group of $Pm\bar{3}m$) is detected in the compositions of $x = 0.1(4.33\%)$ and $x = 0.25(8.01\%)$, which is due to the structure instability induced by the oxygen deficiency. The structure parameters of $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ ($x = 0$, 0.1 and 0.25) are listed in Table 1. The unit cell of the three compositions shrinks with increasing x, reflecting the increasing oxygen vacancies.

However, the situation is quite different in $Sr_5SmTi_{3.2}Nb_{6.8}O_{29.9}$, where a small amount of A2-site Sr cations entered into the smaller A1 site by exchanging equal A1-site Sm cations into A2 site. [001] projection of the unit cell of $Sr_5SmTi_{3.2}Nb_{6.8}O_{29.9}$ shows that O_5 and O_3 are the nearest and next nearest oxygen ions around A1 sites (see Fig. 3(b)). According to ref. 26, in the oxygen-deficient tungsten bronzes $Ba_4Nd_2Ti_{4+2x}Nb_{6-2x}O_{30-x}$, oxygen vacancies locate preferentially in the coordination sphere of Nd and Ti/Nb(2) atoms, which correspond to the areas around A1 sites. It could be suggested that in $Sr_5SmTi_{3.2}Nb_{6.8}O_{29.9}$, oxygen vacancies also prefer to locate at O_3 and O_5 sites, and more Sr cations occupying the A1 sites probably aims to stablize the tetragonal tungsten bronze crystal structure.

The Rietveld refinement using FULLPROF program is performed for the XRD data of composition with $x = 0.1$ ($Sr_5SmTi_{3.2}Nb_{6.8}O_{29.9}$) to get more structure information. The final difference between the experimental data and the calculated data is shown in Fig. 3(a) and final atomic positions and thermal parameters are summarized in Table 2. Relatively higher residuals are obtained ($R_p = 5.77$, $R_{wp} = 7.72$, $R_{exp} = 2.58$ and $\chi^2 = 8.93$), compared with that for $Sr_5SmTi_3Nb_7O_{30}$ ($R_p = 0.0571$, $R_{wp} = 0.0796$, and $\chi^2 = 1.95$).[11] Moreover, other anomalies are found in the atomic distribution of Sr and Sm cations in the A sites and the ultra high thermal parameters (B_{iso} value) obtained for O_1, O_3 and O_5, as shown in Table 2. In $Sr_5SmTi_3Nb_7O_{30}$, 4 Sr cations occupy larger pentagonal A2 sites and extra Sr occupies tetragonal A1 sites together with Sm, as reported in ref. 11. According to $Ba_4Nd_2Ti_{4+2x}Nb_{6-2x}O_{30-x}$, the oxygen vacancies are likely to present associated with O_3 and O_5, which will induce instability in these O sites with higher B_{iso} values. Thus, high B_{iso} values for O_1, O_3 and O_5 here obtained in the $x = 0.1$ composition may also suggest the location of oxygen vacancies.

Table 1 Unit cell parameters and effective tolerance factors for $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$

	$x = 0$	$x = 0.1$	$x = 0.25$
a (Å)	12.3830(7)	12.2920(1)	12.2905(1)
c (Å)	3.8834(2)	3.8686(2)	3.8677(7)
V_{unit} (Å^3)	585.91	584.54	584.26
$\sqrt{10}c/a$	0.9998	0.9952	0.9951

Fig. 4(a)–(c) is the selected area electron diffraction (SAED) patterns of $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$($x = 0$, 0.1 and 0.25) ceramics taken along [110] zone axis at ambient temperature. The fundamental reflections in all patterns of these compounds could be indexed on the tetragonal tungsten bronze (TTB) cell $P\bar{4}bm$. For $Sr_5SmTi_3Nb_7O_{30}$ ($x = 0$), commensurate satellite reflections appears at $h/2$, $k/2$, $l/2$ positions (Fig. 4(a)), which is consistent with the previous report,[14] and the pattern could be indexed using a unit cell with $Ima2$ symmetry $a \approx \sqrt{2}a_{TTB}, b \approx \sqrt{2}a_{TTB}$ and $2c \approx 2c_{TTB}$ according to Levin et al.[5] and Stennett et al.[6] As shown in Fig. 4(b) and (c), up to three-order incommensurate superlattice (ICS) reflections are observed for compositions with $x = 0.1$ and 0.25. The first-order incommensurate superlattice reflections are observed at positions ($h + 1/4 - \delta$, $k + 1/4 - \delta$, $l + 1/2$). The incommensurability parameter δ is the measure of the deviation from commensurate periodicity that is defined as $\delta = (x - y)/(x + y)$, where x and y is the distance of the neighboring incommensurate super-structure spot.[27] The value of δ here is determined as about 0.16 for $x = 0.1$, and 0.10 for $x = 0.25$, which are similar to the δ value determined in $Sr_5LaTi_3Nb_7O_{30}$ ($\delta = 0.12$),[4] but higher than $\delta = 0.04$ reported for $Ba_4La_2Ti_4Nb_6O_{30}$.[5] Actually, δ value of the incommensurate modulation in tungsten bronzes is found to vary in a considerable range. For example, δ value is determined to be 0.050 to 0.034 at 473 to 100 K for $Ba_4La_2Ti_4Nb_6O_{30}$,[5] and 0.059 for $Ba_5LaTi_3Nb_7O_{30}$.[15] For $Sr_{1-x}Ba_xNb_2O_6$,[27] the δ value is decreased from 0.185 to 0.170 as the Ba content increases from

(g)–(i) Schematic diffraction patterns in [110] projection.

0.25 to 0.75. According to Glass,[28] in $Sr_{1-x}Ba_xNb_2O_6$, the increase of Ba/Sr ratio lowers the structure entropy and the development of the incommensurate modulation is believed to reduce the structural energy.[29] Thus, the larger δ value reflects relatively instable structure and disordered cation distribution in tungsten bronze compounds. In the case of commensurate modulation, the δ value is 0. Based on the above analysis, it could be considered that the oxygen deficiency in the present tungsten bronze family induces structure instability and cation disorder, and then results in the incommensurate modulation with similar δ values to that in $Sr_5LaTi_3Nb_7O_{30}$.

Besides, the high structural energy induced by the oxygen deficiency also generates higher-order incommensurate reflections. The commensurate and incommensurate reflections observed in $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ ($x = 0$, 0.1 and 0.25) are furthered verified with line profiles in Fig. 4(d)–(f), respectively,

and corresponding schematic patterns are shown in Fig. 4(g)–(i)). The second-order incommensurate superlattice reflections are observed on the $(00l)$ $(l = 0, 1, 2, 3, …)$ planes around the $(h + 1/2, k + 1/2, l)$ positions for both $x = 0.1$ and 0.25, while the third-order incommensurate superlattice reflections are observed on the $(00l)$ $(l = 1/2, 3/2, …)$ planes, only for $x = 0.25$. Similar high order incommensurate reflections are reported in $Sr_{0.6}Ba_{0.4}Nb_2O_6$ (SBN) with huge large grains and is believed to result from the orthorhombic distortion associated with a shortened c axis, which is originated from the unfavorable occupation of A1 site by some trapped Ba cations during the rapid cooling process, as in the quenched SBN single crystal,[30] and planar defects are detected and is suggested to localize the increase structural energy caused by the orthorhombic distortion and thus stablize the incommensurate phase.[31] According to the results of X-ray diffraction, cross distribution of Sr and Sm cations in the A1 and A2 sites exists in the $x = 0.1$ and 0.25 compositions. The A1 and A2 sites on the $c = 1$ planes, connected directly with O_5, the sites where the oxygen vacancies are preferred, therefore result in a severe distortion of oxygen octahedra. The appearance of higher-order incommensurate reflections in $x = 0.1$ and 0.25 compositions reduces the high structure energy caused by the unusual A-site cation distribution, oxygen vacancies and consequently the distortion of oxygen octahedra.

Temperature dependences of dielectric characteristics are collected for $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ with $x = 0, 0.1$ and 0.25, and shown in Fig. 5(a)–(c). For $x = 0$ composition (Fig. 5(a)), the dielectric permittivity exhibits a sharp peak at about 470 K and a weak relaxation at lower temperature around 250 K, which is consistent with the previous report,[12,13] and indicate a ferroelectric transition with an endothermic peak on heating in the DSC curve shown in Fig. 5(d). For both $x = 0.1$ and 0.25 compositions, a diffuse dielectric peak is observed around 500 K together with an enhanced low temperature relaxation around 200 K. Thus, a wide temperature range (200–500 K) with a stable dielectric constant (~300) is formed and suggests these two compositions as potential temperature stable dielectrics. No DSC peak is observed for these two compositions (see Fig. 5(d)). The low temperature dielectric relaxation can also been observed in the dielectric loss curves with similar intense of $\tan \delta \sim 0.07$ for all the three compositions, and shift to lower temperature with increasing x value. For the relaxation, the frequency dependency of T_m obtained from the dielectric loss $(\tan \delta(T))$ curves can be fitted to the Vogel–Fulcher relationship:

$$F = f_0 \exp[-E_a/k(T_m - T_f)]$$

where f is the applied ac field frequency, f_0 is the Debye frequency, T_f is the static freezing temperature, E_a is the

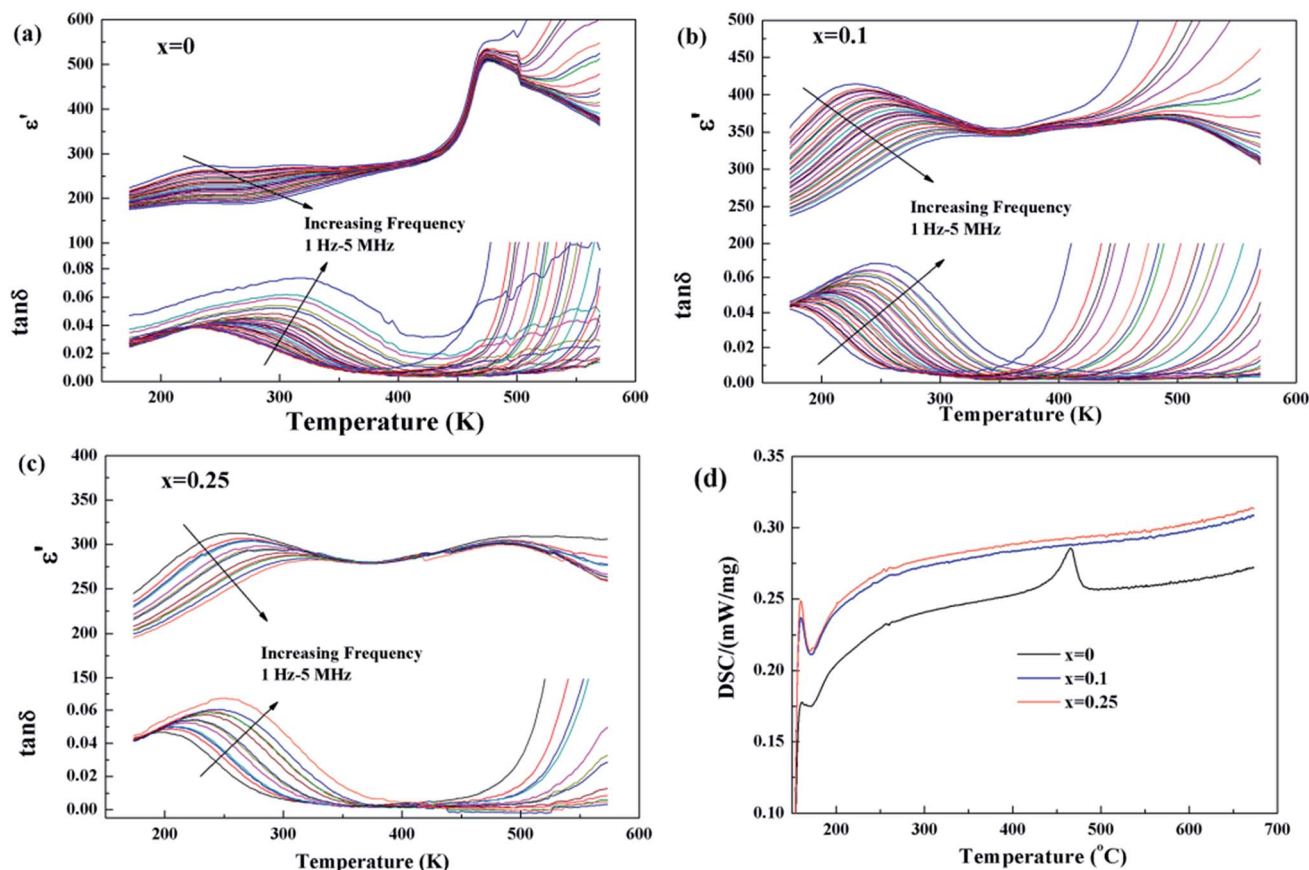

Fig. 5 Dielectric constant ε' and dielectric loss $\tan \delta$ of $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ ceramics as functions of temperature and frequency: (a) $x = 0$; (b) $x = 0.1$; (c) $x = 0.25$, and (d) DSC curves of $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ on heating.
Fig. 6 The frequency dependency of T_m obtained from the dielectric loss (tan $\delta(T)$) curves for $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$, (a) $x = 0$; (b) $x = 0.1$; (c) $x = 0.25$. The red lines indicate the fitting results to the Vogel–Fulcher relation. The fitting parameters are inserted.

Fig. 7 Polarization electric-field (P–E) curves measured at ambient temperature with a triangular wave form at 1 Hz of $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$, (a) $x = 0$; (b) $x = 0.1$; (c) $x = 0.25$.

activation energy of the polar clusters and k is the Boltzmann's constant.[32] The Vogel–Fulcher relationship is interpreted as a normal Debye relaxation with a temperature-dependent activation energy, and indicates the increasing interaction between local random dipolar regions.[32] As shown in Fig. 6, the fitting parameters obtained for $x = 0$ suggesting a freezing process of some low temperature polarization, which is usually observed in tungsten bronze ferroelectrics.[3] However, ultrahigh f_0 values are obtained for the oxygen deficient compositions with $x = 0.1$ and 0.25, which seem unreliable and without physical meanings. Therefore, the low temperature relaxations in compositions with $x = 0.1$ and 0.25 are not a Vogel–Fulcher type relaxation, reflecting the effect of the oxygen deficiency. The weakened ferroelectricity and enhanced relaxation in Sr_5-$SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ with $x = 0.1$ and 0.25 should be related to the random cross distribution in the A sites and the oxygen vacancies induced by the oxygen deficiency.

P–E hysteresis loops for $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ are shown in Fig. 7. Compared with the classic ferroelectric loop obtained for $Sr_5SmTi_3Nb_7O_{30}$ (Fig. 7(a)), almost linear P–E loops are obtained for both $x = 0.1$ and 0.25 when the applied electric field increases up to above 100 kV cm^{-1} (Fig. 7(b) and (c)), reflecting the weakened ferroelectric nature.

Generally, the relation between structure modulation and ferroelectricity in $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ indicates that the normal ferroelectrics exhibit the commensurate modulation (x = 0), while the incommensurate modulation corresponds to the diffuse or relaxor behaviors ($x = 0.1$ and 0.25),as confirmed in many tungsten bronzes, where the structure modulation is dominated by radius difference between A1 and A2 sites.[3–6] In $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ with $x = 0.1$, cross occupancy of Sr and Sm cations in the A1 and A2 sites makes more Sr cations in the A1 sites, leading to smaller radius difference between A1 and A2 sites and thus incommensurate modulation. This is quite different from the situation in $Ba_4Nd_2Ti_{4+2x}Nb_{6-2x}O_{30-x}$, where the A site occupancies are unchanged.[26] Similar to Ba_4Nd_2-$Ti_{4+2x}Nb_{6-2x}O_{30-x}$, there appears to be a change in the non-statistical occupancy of B sites, and the oxygen vacancies are present primarily associated with O_3 and O_5, which are exclusive to B2 site coordination. Then the B2-site Ti cations only have coordination 5 instead of octahedral, and the 5-coordination Ti cannot forms the polar center,[26] thus disrupt the ferroelectric polar domains and dominating the diffuse and relaxor behaviors in $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ with $x = 0.1$ and 0.25. The cross occupancy of Sr and Sm cations in the A1 and A2 sites is probably due to the less stable structure of Sr-based tungsten bronze than the Ba-based one.

4.   Conclusions

Oxygen-deficient $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ (x = 0, 0.1, 0.25) ceramics with tetragonal tungsten bronze structure have been

synthesized and characterized. With increasing oxygen deficiency, the crystal structure become less stable and the lattice shrinks, while the ferroelectricity is weakened, and the low temperature relaxation enhanced. Commensurate modulation is observed in the ferroelectric $Sr_5SmTi_3Nb_7O_{30}$ ($x = 0$), while three orders of incommensurate satellite reflections are observed for compositions with $x = 0.1$, 0.25, and is believed to reduce the structural energy induced by the oxygen deficiency. Two factors are considered to understand the change from ferroelectric behavior to diffuse one. Firstly, the A site cross occupancy leads to smaller radius difference between A1 and A2 sites. Secondly, non-polar 5-coordination Ti cations caused by the O(3,5) vacancies interrupt the ferroelectric polar domains. Moreover, $Sr_5SmTi_{3+2x}Nb_{7-2x}O_{30-x}$ ceramics with $x = 0.1$ and 0.25 may be very good candidates for temperature-stable dielectrics with dielectric constant $\sim$300, and very low tan $\delta <$ 0.02 in a wide temperature range from 200 K to 500 K.
