Synthesis, structure and reactivity of guanidinate rare earth metal bis(o-aminobenzyl) complexes†

Feng Kong, Meng Li, Xigeng Zhou* and Lixin Zhang

A series of guanidinate rare-earth metal complexes \([\{(\text{PhCH}_2)\text{N}[\text{C(NHR)}]_2\}2 \text{RE} = \text{Y (2a), La (2b), Dy (2c), Lu (2d)}]\) were synthesized by the acid–base reaction of \(\text{RE}(\text{CH}_2\text{C}_6\text{H}_4\text{NMe}_2\text{-o})_3\) with \(\{(\text{PhCH}_2)\text{N}[\text{C(NHR)}]_2\}2 \text{Y = Y (3a), La (3b), Dy (3c), Lu (3d)}\). Treatment of complexes 2 with two equivalents of carbon dioxide, sulfur and phenyl isothiocyanate gave the corresponding insertion products \((\{(\text{PhCH}_2)\text{N}[\text{C(NR)}]_2\}2\text{RE}(\text{CH}_2\text{C}_6\text{H}_4\text{NMe}_2\text{-o})_2\) with \(\{(\text{PhCH}_2)\text{N}[\text{C(NHR)}]_2\}2\text{RE}(\text{CH}_2\text{C}_6\text{H}_4\text{NMe}_2\text{-o})_2\).

1. Introduction
Since the first structural characterization of a half sandwich rare-earth bis[allyl] complex was reported by Schaverien in 1989, rare-earth dialkyl complexes have demonstrated great potential applications in synthetic chemistry and polymerization. The reported results indicated that the proper design of the coligand is of great importance and can not only improve the stability of rare-earth bis[allyl] complexes but also influence their reactivity. Recently, many of rare-earth complexes with non-Cp ancillary ligands were explored. Among various non-Cp ligands, amidinate and guanidinate stand out and are widely employed in lanthanide chemistry because of their tunable steric and electronic properties, rich coordination mode and easy accessibility. Guanidinate scaffolds are of tremendous popularity in lanthanide chemistry and numerous rare-earth complexes bearing guanidinate ligands have been reported. However, just a handful of neutral monoguanidinate bis[allyl] rare-earth complexes were synthesized. And neither their reactivity towards small molecules nor their performance as precatalyst towards conjugated diene polymerization have been unveiled so far.

Recently, our group reported the reactions of amidinate rare-earth dialkyl complexes with various small molecules, which not only shed some light on the reaction chemistry of amidinate rare-earth dialkyl complexes, but also provided different options for the synthesis of some organolanthanide derivatives.

2. Results and discussion
2.1 Synthesis of \(\{(\text{PhCH}_2)\text{N}[\text{C(NHR)}]_2\}2 \text{RE} = \text{Y (4a), La (4b), Dy (4c), Lu (4d)}\) and \(\{(\text{PhCH}_2)\text{N}[\text{C(NR)}]_2\}2\text{RE}(\text{SC(CH}_2\text{C}_6\text{H}_4\text{NMe}_2\text{-o})_2\text{NPh})_2\) in good yields, respectively. All new complexes were fully characterized by NMR spectroscopy and elemental analysis. The structures of 1, 2d, 3a, 4a, 4c–d, 5a, and 5c–d were established by X-ray diffraction studies. Complexes 2 were found to have a high activity and excellent 3,4-selectivity for isoprene polymerization in the presence of [Ph$_3$C][B(C$_6$F$_5$)$_3$].

In order to further explore the effect of subtle ligand change on the reaction patterns of rare-earth bis[alkyl] complexes, we designed a new bulky tetraalkylated guanidinate with two benzyl groups at the axis N atom. Herein, we report the synthesis of this new guanidine and the corresponding rare-earth bis[alkyl] complexes. The reactions of the dialkyl species with small molecules, such as CO$_2$, S$_8$, and PhNCS are also disclosed. Moreover, the catalytic performance of the monoguanidinate rare-earth bis[alkyl] complexes for isoprene polymerization will be discussed as well.

units. Besides, we further collected the NMR spectra of 1 in C6D6, and in the 1H NMR spectrum (in C6D6) of 1, the signals of methine protons in –CHMe2 units appear as multiple peaks at δ = 3.50 and 3.35 ppm. In its 13C NMR spectrum (in C6D6), corresponding carbon resonances appear at δ = 29.3 and 28.6 ppm respectively.

2.2 Synthesis of [(PhCH2)2NC(NC6H4Pr2,6-d)3]RE
(CH3C6H4NMe2-o)2 (RE = Y (2a), La (2b), Dy (2c), Lu (2d))

As shown in Scheme 2, treatment of RE(CH3C6H4NMe2-o)2 with 1 afforded the guanidinate-stabilized bis(aminobenzyl) complexes [(PhCH2)2NC(NC6H4Pr2,6-d)3]RE(CH3C6H4NMe2-o)2 (RE = Y (2a), La (2b), Dy (2c), Lu (2d)) in moderate yields. All the new compounds were characterized by elemental analysis, NMR spectroscopy (except for 2c). In 1H NMR spectra of 2, the resonances of the methylene protons in aminobenzyl group appear as sharp singlets at δ = 1.81(2a), 1.84(2b) and 1.80(2d) ppm respectively. And the signals at δ = 48.0(2a), 61.6(2b) and 53.3(2d) in their 13C NMR spectra can be assigned to their corresponding methylene carbons. And the signals of methine protons in the guanidinate ligand of the complexes 2 are observed at δ = 5.29(2a) and 5.32 ppm for 2b, 5.33 ppm for 2b and 5.27 ppm for 2d, while their corresponding carbon resonances almost remain unchanged, the similar phenomenon was observed in [(CH3)2NC(NC6H4Pr2,6-d)3]Y(CH3SiMe3)2(THF) and the corresponding neutral ligand (CH3)2NC(NH)(=N)[R (2a), RE = Y (2a)] or (R = 2,6-Pr2C6H3). Other characteristic peaks can also be assigned clearly. Single crystal X-ray structural analysis of complex 2d established the distorted-octahedral geometry of its core structure. The structure of 2d is depicted in Fig. 2; selected bond lengths and angles are listed in the caption. The lutetium atom was coordinated by six atoms: two nitrogen atoms from the guanidinate ligand, two carbon atoms and two amino nitrogen atoms. The guanidinate ligand coordinates symmetrically to the Lu atom. Because of the better symmetry of the coordinated guanidinate ligand, the numbers of the methine and methyl resonances of the ligand decrease in the NMR spectra of complexes 2 in comparison with the neutral ligand. The bond length of Lu–N (2.318(3) Å) is very close to the Lu–N distance in [CyC(N,2,6-Pr2C6H3)2]Lu(CH3SiMe3)2(THF) (average 2.313 Å) and slightly shorter than Y–N distance (2.373 Å) in [PhC(NC6H4Pr2,6-d)3]Y(CH3C6H4NMe2-o)2 after taking into consideration of the difference between metal radii.

2.3 Reaction of [(PhCH2)2NC(NC6H4Pr2,6-d)3]RE
(CH3C6H4NMe2-o)2 (RE = Y (2a), La (2b), Dy (2c), Lu (2d)) with CO2

To explore the ligand effect on the structure and reactivity of complexes, reactions of complexes 2 with CO2 were conducted firstly. The THF solution of complexes 2 was stirred under an atmosphere of CO2 (0.1 MPa), an immediate colour change from yellow to colourless was observed for complexes 2b and 2c, while the colour change was not observed in the reaction of 2a.
and 2d (Scheme 3). Expected insertion products \([\{\{\text{PhCH}_2\}_n\text{NC}(\text{NC}_6\text{H}_4\text{Pr}_2-2,6)_{2}\}\text{RE}[\mu-\eta^2:\eta^1-\text{O}_2\text{CCH}_2\text{C}_6\text{H}_4\text{NMe}_2-0]\{\mu-\eta^1:\eta^1-\text{O}_2\text{CCH}_2\text{C}_6\text{H}_4\text{NMe}_2-0\}]_2\) (RE = Y (3a), La (3b), Dy (3c), Lu (3d)) were obtained in medium to excellent yields. In their \(^1\)H NMR spectra, the broad peak observed at \(\delta = 3.47(3b), 3.50(3d)\) ppm can be assigned to methylene protons of the aminobenzyl groups. Complex 3b displays a sharp singlet at \(\delta = 2.54\) ppm assignable for the methyl protons of \(-\text{NMe}_2\) groups, while for 3d, the methyl signal turns into a set of broad multiple peaks at \(\delta = 2.52\) ppm. However, in the room temperature \(^1\)H NMR spectrum of 3a, there is only one broad peak at \(\delta = 2.47\) ppm that can be assigned to methylene and methyl protons in the aminobenzyl groups. Compared to their corresponding dialkyl complexes, in complexes 3 (except 3c), the methylene protons of the aminobenzyl groups obviously shift to downfield which indicates the insertion of CO\(_2\) molecules. And in their \(^1\)C NMR spectra, the resonances at \(\delta = 186.2(3a), 183.6(3b)\) and 183.7(3d) ppm are assignable to the carbons in carboxyl groups. The structures of complexes 3 were further confirmed by the X-ray single crystal diffraction. The X-ray crystallographic analysis indicates that complexes 3a-d are isostructural, and crystal structure of 3a is presented in Fig. 3. The generated carboxyl groups coordinate to lanthanide centres in two different fashions: \(\mu-\eta^1:\eta^1\) and \(\mu-\eta^2:\eta^1\). And the C-O bond lengths of complexes 3 range from 1.222(9) Å to 1.309(8) Å, which are consistent with typical delocalized carboxylate species.\(^9\) The Y-O bond length are generally in the normal range except the Y(1)-O(3A) (2.737(4) Å) bond. The Y(1)-O(3A) bond is remarkably longer than those observed in \([\{\text{C}_2\text{Me}_3\text{SiMe}_2(\text{CH}_2\text{CH}=\text{CH}_2)]\{\mu-\eta^2:\eta^1-\text{O}_2\text{CCH}_2\text{SiMe}_3\}]_2\) (ref. 9b) (2.563(2) Å) and \([\{\text{PhC}(\text{NC}_6\text{H}_4\text{Pr}_2-2,6)_{2}\}{\mu-\eta^2:\eta^1-\text{O}_2\text{CCH}_2\text{C}_6\text{H}_4\text{NMe}_2-0}\{\mu-\eta^1:\eta^1-\text{O}_2\text{CCH}_2\text{C}_6\text{H}_4\text{NMe}_2-0\}]_2\) (2.53(1) Å).\(^7\) This unusual bond length can be ascribed to the bulky size and electronic effect of the guanidinate ligand. The poor solubility of complexes 3 even in THF at room temperature can provide extra evidence for the sterically crowded coordination sphere around the lanthanide centres. The reactions of complexes 2 with CO\(_2\) provide not only an effective way for the activation of CO\(_2\), but also a good synthetic method for guanidinate rare-earth derivatives.

2.4 Reaction of \([\{\text{PhCH}_2\}_n\text{NC}(\text{NC}_6\text{H}_4\text{Pr}_2-2,6)_{2}\}\text{RE}(\text{CH}_2\text{C}_6\text{H}_4\text{NMe}_2-0)]_2\) (RE = Y (2a), La (2b), Dy (2c), Lu (2d)) with S\(_8\)

To further study the reactivity of complexes 2, reactions with S\(_8\) were also carried out. Different from their amindinate counterparts,\(^7\) the reactions of complexes 2 with 1/4 equivalent S\(_8\) gave dinuclear lanthanide insertion products \([\{\text{PhCH}_2\}_n\text{NC}(\text{NC}_6\text{H}_4\text{Pr}_2-2,6)_{2}\}\text{RE}[\mu-\eta^1:\eta^1-\text{O}_2\text{CCH}_2\text{C}_6\text{H}_4\text{NMe}_2-0]_{2}\] (RE = Y (4a), La (4b), Dy (4c), Lu (4d)) in good yields (Scheme 4).\(^11\) These complexes are easily soluble in toluene and THF, and slightly soluble in hexane. Complexes 4a, 4b and 4d were characterized by the \(^1\)H and \(^13\)C NMR spectra in C\(_6\)D\(_6\) at 25 °C. The \(^1\)H NMR spectra show multiple signals at \(\delta = 3.89(4a), 3.77(4b)\) and 3.95(4d) ppm which are assignable for the methine protons of the CHMe\(_2\) groups. Compared to their corresponding dialkyl complexes, the signals of the methylene protons obviously shift to lower field because of the insertion of the sulfur atoms. For 4b, the signal for the methylene protons of aminobenzyl group appears as a sharp singlet at \(\delta = 4.52\) ppm, while for 4a and 4d, it becomes a broad peak at \(\delta = 4.28\) and 4.46 ppm respectively. And their corresponding carbon signals show up at \(\delta = 34.6(4a), 33.5(4b)\) and 34.3(4d) ppm as sharp singlets. The X-ray single crystal diffraction analysis established the bimetallic structure of complexes 4a, 4c and 4d (Fig. 4). Two yttrium ions are connected by four bridging thiolate units which definitely proves the insertion of sulfur atoms into each of Y-C bonds. In lanthanide chemistry, the similar core
structure is only observed in complex $[\text{BuC}(\text{NC}_6\text{H}_4\text{H}_4\text{Pr}_2-2,6)]\text{Yb}[\mu-\text{SCH}_2\text{Ph}]_2$.$^{11}$ The lengths of Y–S bonds range from 2.778(1) Å to 2.841(1) Å and are comparable to the previously reported Y–S($\mu_2$-SR) bonds.$^{26}$ The dihedral angles between the Y1S1Y2 and Y1S2Y3 plane is 179.7°, indicating that the Y1S1Y2S3 is coplanar. Y1S2Y3S4 unit is also coplanar. Besides, the two planes are almost vertical to each other with a dihedral angle of 89.86°.

2.5 Reaction of $[(\text{PhCH}_3)_2\text{NC}(\text{NC}_6\text{H}_4\text{H}_4\text{Pr}_2-2,6)]\text{RE}\left(\text{CH}_2\text{C}_6\text{H}_4\text{NMe}_2-\text{O}\right)_2$ (RE = Y (2a), La (2b), Dy (2c), Lu (2d)) with PhNCS

The reactivity of complexes 2 towards phenyl isothiocyanate was also studied. These reactions provided insertion products $[(\text{PhCH}_3)_2\text{NC}(\text{NC}_6\text{H}_4\text{H}_4\text{Pr}_2-2,6)]\text{RE}\left[\text{SC}(\text{CH}_2\text{C}_6\text{H}_4\text{NMe}_2-\text{O})\text{NPh}_2\right]_2$ (THF)$_n$ ($n = 1$, RE = La (5b); $n = 0$, RE = Y (5a), Dy (5c), Lu (5d)) in 46–77% yields (Scheme 5). Compared to the guanidinate dialkyl complexes 2, the resonances of methylene protons in aminobenzyl groups of these insertion products shift from upfield to downfield $\delta = 4.14$ for 5a, 4.17 for 5b and 4.15 for 5d ppm respectively. In their $^{13}$C NMR spectra, the corresponding signals were observed at $\delta = 42.4(5a), 43.2(5b)$ and 42.6(5d) ppm as singlets. Complex 5b is of high solubility even in hexane while 5a, 5c and 5d are sparingly soluble in hexane. Noticeably, the larger lanthanum bears one coordinated THF molecule, while complexes 5a, 5c and 5d are all solvent free mononuclear complexes. As shown in Fig. 5, the yttrium ion of 5a is surrounded by four nitrogen atoms, two from the guanidinate ligand, two from the NCS fragments and two sulfur atoms from the NCS moieties. The Y–S bond length of 2.7154(9) Å is identical with the corresponding distances in 1,4-C$_5$H$_4$H$_4$[C(NR)$_2$Y[SC(CHO)$_4$H$_4$NMe$_2$-O][NPh]$_2$]$_2$ (ref. 7a) (2.71 Å) and $[(\text{CH}_2\text{C}_6\text{H}_4)_2\text{Y}[\eta^3\text{SC}(\text{NPH}_2)\text{NPh}]]_2$ (2.7847(8) Å).$^{12}$ The S1–C21 and N3–C21 distances, 1.735(3) and 1.287(4) Å, are between the corresponding single and double bond lengths, respectively, indicating that the negative charge is delocalized over the N–C–S moiety.$^{13}$

2.6 Polymerization of isoprene

Complexes 2 were also evaluated as precatalysts for the polymerization of isoprene, and the results are presented in Table 1. Complexes 2 were inert towards the polymerization of isoprene. The binary system comprised of 2a (2c or 2d)/$\text{PhC}[\text{B}(\text{C}_6\text{F}_5)_4]$ (1 : 1) displayed a high catalytic activity and predominant 3,4-regioselectivity for isoprene polymerization at room temperature (entries 1 to 4). But significant catalytic activity drop was observed for the lanthanum binary system (entry 2), probably due to the lower Lewis acidity compared to Y, Dy and Lu ions. Molecular weight distributions of all the polymers obtained from these binary systems are very narrow and unimodal (1.03–1.05) (entries 1 to 8). Further kinetics study on yttrium binary system was carried out and displayed in Fig. 6. It is noteworthy that the number-average molecular weight ($M_n$) of the yielded
polymer samples was linearly relative to the conversion. In the meanwhile, the molecular weight distribution ($M_w/M_n$) was almost constant (1.03 to 1.07). The kinetics study indicated that the binary system $2a/[\text{Ph}_3\text{C}][\text{B(C}_6\text{F}_5)_4]$ demonstrated characteristics of living polymerization. To the best of our knowledge, examples of isoprene living polymerization with high 3,4-regioselectivity remain relatively rare. Moreover, the reaction temperature also influenced the polymerization performance. When the polymerization was carried out at 0 °C (entry 9), the yielded polymer showed the higher proportion of 3,4 units (93%). At −20 °C (entries 10−14), although the activity apparently dropped, it took 24 hours for $2a/[\text{Ph}_3\text{C}][\text{B(C}_6\text{F}_5)_4]$ system to get 100% conversion, the higher 3,4-regioselectivity (99%) was achieved and the yttrium binary system still demonstrates characteristics of living polymerization (Fig. 7). Interestingly, in contrast to the binary system comprised of $2a/[\text{Ph}_3\text{C}][\text{B(C}_6\text{F}_5)_4]$, it was found that the ternary system $2a/[\text{Ph}_3\text{C}][\text{B(C}_6\text{F}_5)_4]/\text{AlMe}_3$ (1 : 1 : 5) showed a high cis-1,4-regioselectivity (entry 15). However, the introduction of $\text{AlBu}_3$ to the $2a/[\text{Ph}_3\text{C}][\text{B(C}_6\text{F}_5)_4]$ system led to the formation of polymer blend (entry 16).

3. Conclusions

In summary, a series of neutral mono(guanidinate) rare-earth bis(alkyl) complexes have been synthesized via the protolysis reaction of homeolitic rare-earth alkyl complexes with one equimolar amount of a new bulky guanidine. The reactions of bis(aminobenzyl) complexes with CO$_2$, $\text{S}_8$ and $\text{PhNCS}$ provide some new options for effective synthetic routes for guanidinate lanthanide derivatives. Moreover, upon activation of an organoborate, such as $[\text{Ph}_3\text{C}][\text{B(C}_6\text{F}_5)_4]$, complexes 2 show excellent activity and predominant 3,4-selectivity towards isoprene.
polymerization in a living fashion, whereas the ternary system 2a[Ph3C][B(C6F5)4]/AlMe3 (1:1:5) showed a high cis-1,4-regioselectivity.

4. Experiment section

4.1 Materials and general procedures

All manipulations involving air- and moisture sensitive compounds were performed under an inert atmosphere of purified nitrogen with rigorous exclusion of air and moisture using standard Schlenk techniques and a nitrogen filled glove box operating at less than 1 ppm oxygen and 1 ppm moisture. Solvents (toluene, hexane, and THF) were distilled from sodium/benzophenone ketyl, and dried over fresh Na chips in the glove box. Bis[2,6-diisopropylphenyl]carbodiimide was obtained from Tokyo Chemical Industry Co., Ltd and used without purification. CH4C6H5NMe2 was purchased from Acros and used without purification. BuLi (2.5 mol L−1 in hexane), AlMe3 (1 mol L−1 in hexane) and AlBu3 (1 mol L−1 in hexane) were purchased from J&K and used without purification. Phenyl isothiocyanate were purchased from Dar Rui and distilled from CaH2 before being used. Highly pure CO2 gas (99.99%) was obtained from Cambridge Isotope and dried by sodium chips. Isoprene was obtained from Tokyo Chemical Industry Co., Ltd and purified by distillation over CaH2 under a nitrogen atmosphere. C6D6 and CDCl3 was activated 4 at 80 °C under a nitrogen atmosphere. C6D6 and CDCl3 was activated 4 at 80 °C under a nitrogen atmosphere.

4.2 X-ray crystallographic analysis

Suitable crystals were sealed in thin-wall glass capillaries under a microscope in the glove box. Data collections were performed on a Bruker SMART APEX diffractometer with a CCD area detector using graphite-monochromated MoKα radiation (λ = 0.71073 Å). The determination of crystal class and unit cell was carried out by the SMART program package. The raw frame data were processed using SAINT and SADABS to yield the reflection data file. The structure was solved by using SHELXTL program. Refinement was performed on F2 anisotropically by the full-matrix least-squares method for all the non-hydrogen atoms. The analytical scattering factors for neutral atoms were used throughout the analysis. For the hydrogen atoms on bridging-carbons, hydrogen atoms were placed at the calculated positions and included in the structure calculation without further refinement of the parameters. The hydrogen atoms on bridging carbons were located by difference Fourier syntheses and their coordinates and isotropic parameters were refined. The disordered toluene and THF molecules within the crystal lattice are not crystallographically well defined and are squeezed by the PLATON program. Details of this SQUEEZE are given in the cif files. Residual electron densities were of no chemical significance. Crystal data, data collection, and processing parameters for complexes 2b, 3a, 4a and 5a are summarized in Table 2. CCDC – 1542242 (1), 893571 (2d), 1541968 (3a), 1541967 (3b), 1541964 (3c), 1541970 (3d), 1541962

4.4 Synthesis of [(PhCH2)2NC(NH)2](NC(NH)2) (1)

A 6BuLi solution (10.0 mmol, 4 mL, 2.5 M in hexane) was added slowly to a stirred solution of [(PhCH2)2NH • H2O] (1.97 g, 10.0 mmol) in THF (30 mL) at room temperature, then stirred for 2 h. Subsequently, the solution of the in situ (PhCH2)2NLI was added to a stirred THF solution of bis(2,6-diisopropylphenyl) carbodiimide (3.63 g, 10.0 mmol) at room temperature, the mixture was stirred for 4 h and added slowly the distilled water to afford a clear orange solution. All volatiles were removed under vacuum. The residue was washed with water, and the product was extracted with hexane (3 × 25 mL), all volatiles were removed under vacuum, and the yellowish powder was recrystallized in hexane at −35 °C to give colourless crystals (4.53 g, 81%).

A THF solution (10 mL) of Y(CH2C6H4NMe2−(OAc) (3.63 g, 10.0 mmol) was added into a stirred THF solution of bis(2,6-diisopropylphenyl) carbodiimide (3.63 g, 10.0 mmol) at room temperature, the mixture was stirred for 4 h and added slowly the distilled water to afford a clear orange solution. All volatiles were removed under vacuum. The residue was washed with water, and the product was extracted with hexane (3 × 25 mL), all volatiles were removed under vacuum, and the yellowish powder was recrystallized in hexane at −35 °C to give colourless crystals (4.53 g, 81%).

**Synthesis of [(PhCH2)2NC(NH)2](NC(NH)2) (2a)***

A THF solution (10 mL) of Y(CH2C6H4NMe2−(OAc) (0.25 g, 0.5 mmol) in THF (10 mL) was added into a stirred solution (20 mL) of [(PhCH2)2N[C(NH)2](N)[(N)] (0.10 g, 0.28 g, 0.5 mmol) in THF. The reaction solution was left to stir for 2 days at 65 °C, and all volatiles were removed under vacuum. The oily residue was washed with cold hexane and pale yellow powder was obtained by filtration. The powder was recrystallized in toluene at −35 °C for 2 days to give white powder of 2a (0.30 g (65%).

**13C NMR (100 MHz, CDCl3, 298 K):** δ = 161.3 (NCN), 154.5 (d, J = 26 Hz, Ar), 144.2 (s, Ar), 141.8 (s, Ar), 136.0 (s, Ar), 129.9 (s, Ar), 127.4 (s, Ar), 126.7 (s, Ar), 124.4 (s, Ar), 123.8 (s, Ar), 120.8 (s, Ar), 118.2 (s, Ar), 53.2 (s, -CH2Ph), 48.0 (d, J = 20 Hz, -CH2C6H4NMe2), 46.6 (br s, -NMe2), 29.1 (s, -CHMe2), 24.7 (s, -CHMe2), 24.2 (br s, -CHMe2).

**Calcd for C27H23N2Y (%): C, 74.73; H, 7.92; N, 7.64; found: C, 75.25; H, 7.76; N, 7.20.***
4.8 Synthesis of \([(\text{PhCH}_2)_2\text{NC(NC}_6\text{H}_4\text{Pr}_2-2,6)_2\text{Y}](\mu-\eta^3:\eta^1-\text{O}_2\text{CCH}_2\text{C}_6\text{H}_4\text{NMe}_2-o)(\mu-\eta^3:\eta^1-\text{O}_2\text{CCH}_2\text{C}_6\text{H}_4\text{NMe}_2-o)]_2\) (3a)

A THF (10 mL) solution of complex 3a (0.46 g, 0.5 mmol) was concentrated to dryness. The residue was recrystallized in toluene at room temperature for 2 days. The white powder was recrystallized in toluene which then was collected by filtration. The white powder was recrystallized in toluene at room temperature for 2 days to give a colourless crystalline complex 3b (0.38 g (77%).

4.9 Synthesis of \([(\text{PhCH}_2)_2\text{NC(NC}_6\text{H}_4\text{Pr}_2-2,6)_2\text{La}(\mu-\eta^3:\eta^1-\text{O}_2\text{CCH}_2\text{C}_6\text{H}_4\text{NMe}_2-o)(\mu-\eta^3:\eta^1-\text{O}_2\text{CCH}_2\text{C}_6\text{H}_4\text{NMe}_2-o)]_2\) (3b)

Complex 3b was obtained as a colourless crystalline product (0.38 g, 73%), similarly to the preparation of 3a described above.

4.10 Synthesis of \([(\text{PhCH}_2)_2\text{NC(NC}_6\text{H}_4\text{Pr}_2-2,6)_2\text{Dy}(\mu-\eta^3:\eta^1-\text{O}_2\text{CCH}_2\text{C}_6\text{H}_4\text{NMe}_2-o)(\mu-\eta^3:\eta^1-\text{O}_2\text{CCH}_2\text{C}_6\text{H}_4\text{NMe}_2-o)]_2\) (3c)

Complex 3c was obtained as a colourless crystalline product (0.47 g, 88%), similarly to the preparation of 3a described above.
4.14 Synthesis of \([\text{[PhCH}_3\text{]}_2\text{NC(NC}_6\text{H}_4\text{Pr}_2\text{-2,6}]_2\text{]Dy}\) 
\([\mu-\text{S}-(\text{CH}_2\text{C}_6\text{H}_4\text{NMe}_2\text{-o})_2]\) (4c)

Complex 4c was obtained as a colourless crystalline product (0.38 g, 73%), similarly to the preparation of 4a described above. Calcd for C_{114}H_{144}N_{10}S_{4}Lu_{2} (%): C, 64.65; H, 6.88; N, 6.65; found: C, 64.84; H, 6.83; N, 6.73.

4.15 Synthesis of \([\text{[PhCH}_3\text{]}_2\text{NC(NC}_6\text{H}_4\text{Pr}_2\text{-2,6}]_2\text{]Lu}\) 
\([\mu-\text{S}-(\text{CH}_2\text{C}_6\text{H}_4\text{NMe}_2\text{-o})_2]\) (4d)

Complex 4d was obtained as a colourless crystalline product (0.36 g, 67%), similarly to the preparation of 4a described above. Calcd for C_{71}H_{82}N_{7}S_{2}Lu (%): C, 70.97; H, 7.34; N, 8.08; found: C, 70.97; H, 7.34; N, 8.08.

4.16 Synthesis of \([\text{[PhCH}_3\text{]}_2\text{NC(NC}_6\text{H}_4\text{Pr}_2\text{-2,6}]_2\text{]Y}\) 
\(\{\text{SC(CH}_2\text{C}_6\text{H}_4\text{NMe}_2\text{o})_2\}\) (5a)

A THF (10 mL) solution of PhNCS (0.108 mL, 1 mmol) was added slowly to a stirred THF (20 mL) solution of complex 2a (0.46 g, 0.5 mmol). The reaction solution was left to stir at room temperature for 12 h and all volatiles were removed under vacuum. After being washed with cold hexane, the oily residue turned to white powder which then was collected by filtration and dissolved in toluene. The solution was concentrated to saturation and layerd with 2 mL hexane solvent. White precipitate 5a was obtained after the solution stood at -35 °C for 3 days. Yield (0.28 g, 46%). \(^1\)H NMR (400 MHz, C_{6}D_{6}, 25 °C): \(\delta = 7.72-7.70\) (m, 2H, Ar), 7.13-7.08 (m, 8H, Ar), 7.03-6.82 (m, 22H, Ar), 6.37 (d, \(J = 8\) Hz, 4H, Ar), 4.17 (s, 4H, -CH_{2}C_{6}H_{4}NMe_{2}-o), 4.12 (s, 4H, -CHPh), 3.98 (m, 4H, -CH_{2}C_{6}H_{4}NMe_{2}-o), 2.36 (s, 12H, -NMe_{2}), 2.45 (m, 4H, -CHMe_{2}), 27.0 (s, -CH_{2}C_{6}H_{4}NMe_{2}-o), 25.3 (s, -CHMe_{2}), 24.1 (s, -CHMe_{2}). Calcd for C_{29}H_{30}N_{6}S_{2}O_{2} (%): C, 68.84; H, 6.93; N, 7.49; found: C, 68.70; H, 7.06; N, 7.73.

4.17 Synthesis of \([\text{[PhCH}_3\text{]}_2\text{NC(NC}_6\text{H}_4\text{Pr}_2\text{-2,6}]_2\text{]La}\) 
\(\{\text{SC(CH}_2\text{C}_6\text{H}_4\text{NMe}_2\text{o})_2\}(\text{THF})\) (5b)

A THF (10 mL) solution of PhNCS (0.108 mL, 1 mmol) was added slowly to a stirred THF (20 mL) solution of complex 2b (0.48 g, 0.5 mmol). The reaction solution was left to stir at room temperature for 12 h and all volatiles were removed under vacuum. After being washed with cold hexane, the oily residue turned to white powder which then was collected by filtration and dissolved in toluene. The solution was concentrated to saturation and layered with 2 mL hexane solvent. White precipitate 5b was obtained after the solution stood at -35 °C for 3 days. Yield (0.28 g, 44%). \(^{1}\)H NMR (400 MHz, C_{6}D_{6}, 25 °C): \(\delta = 7.79-7.76\) (m, 2H, Ar), 7.15-7.10 (s, 8H, Ar), 7.03-6.82 (m, 22H, Ar), 6.37 (d, \(J = 8\) Hz, 4H, Ar), 4.17 (s, 4H, -CH_{2}C_{6}H_{4}NMe_{2}-o), 4.12 (s, 4H, -CHPh), 3.98 (m, 4H, -CH_{2}C_{6}H_{4}NMe_{2}-o), 2.36 (s, 12H, -NMe_{2}), 2.45 (m, 4H, -CHMe_{2}), 27.0 (s, -CH_{2}C_{6}H_{4}NMe_{2}-o), 25.3 (s, -CHMe_{2}), 24.1 (s, -CHMe_{2}). 4.18 Synthesis of \([\text{[PhCH}_3\text{]}_2\text{NC(NC}_6\text{H}_4\text{Pr}_2\text{-2,6}]_2\text{]Dy}\) 
\(\{\text{SC(CH}_2\text{C}_6\text{H}_4\text{NMe}_2\text{o})_2\}\) (5c)

Complex 5c was obtained as a colourless crystalline product (0.44 g, 47%), similarly to the preparation of 5a described above. Calcd for C_{75}H_{90}N_{7}S_{2}Dy (%): C, 68.84; H, 6.93; N, 7.78; found C, 67.59; H, 6.87; N, 7.80.

4.19 Synthesis of \([\text{[PhCH}_3\text{]}_2\text{NC(NC}_6\text{H}_4\text{Pr}_2\text{-2,6}]_2\text{]Lu}\) 
\(\{\text{SC(CH}_2\text{C}_6\text{H}_4\text{NMe}_2\text{o})_2\}\) (5d)

Complex 5d was obtained as a colourless crystalline product (0.41 g, 65%), similarly to the preparation of 5a described above. Calcd for C_{117}H_{149}N_{10}S_{4}Lu (%): C, 71.87; H, 6.97; N, 8.26; found: C, 71.87; H, 6.97; N, 8.26.
4.20 Typical procedure for polymerization of isoprene

The procedures for isoprene polymerization were similar, thus take complex 2a as an example and corresponding polymerization procedure is given below. For 2a[(Ph$_3$C)$_2$B(C$_6$F$_5$)$_3$] binary system: in a glovebox, a magnetic stir bar was placed in a 100 mL flask, to which a dropping funnel was attached. Isoprene (1.022 g, 15 mmol), 3,4-rich polyisoprene (1.022 g, 15 mmol), [B(C$_6$F$_5$)$_4$] (0.0185 g, 0.020 mmol) and C$_6$H$_5$Cl (8 mL) were charged into the flask. A C$_6$H$_5$Cl solution (2 mL) of [Ph$_3$C][B(C$_6$F$_5$)$_3$] (0.0185 g, 0.020 mmol) was charged to the dropping funnel. The reaction apparatus was moved outside and placed in a water bath (25 °C). After 10 min, the C$_6$H$_5$Cl solution of [Ph$_3$C][B(C$_6$F$_5$)$_3$] was dropped into the mixture of 2a and isoprene under rapid stirring. After the mixture was stirred at 25 °C for 10 min, methanol was injected to terminate the polymerization. The reaction mixture was poured into a large funnel. The reaction apparatus was moved outside and placed in a water bath (25 °C). After 10 min, the C$_6$H$_5$Cl solution of [Ph$_3$C][B(C$_6$F$_5$)$_3$] was dropped into the mixture of 2a and isoprene under rapid stirring. After the mixture was stirred at 25 °C for 10 min, methanol was injected to terminate the polymerization. The reaction mixture was cooled to a constant weight to a known final weight and washed with methanol, and then dried under vacuum at 60 °C to a constant weight to afford 1.02 g of 3,4-rich polyisoprene (~100% yield). For 2a[(Ph$_3$C)$_2$B(C$_6$F$_5$)$_3$]/AlR$_3$ ternary systems: isoprene (1.022 g, 15 mmol), 2a (0.018 g, 0.020 mmol), AlR$_3$ (100 mL, 1 mol L$^{-1}$ in hexane) and C$_6$H$_5$Cl (8 mL) were charged into the flask and other operations are same as above-mentioned binary system.
