First-principles study of decomposition mechanisms of $Mg(BH_4)_2 \cdot 2NH_3$ and $LiMg(BH_4)_3 \cdot 2NH_3$

Xiaowei Chen, ^{Dab} Renquan Li,^a Guanglin Xia, ^{Dc} Hongsheng He,^a Xiuqing Zhang,^a Weidong Zou^{*a} and Xubin Yu^{*b}

The decomposition mechanisms of $Mg(BH_4)_2 \cdot 2NH_3$ and $LiMg(BH_4)_3 \cdot 2NH_3$ were studied by using density functional theory calculations. Compared to that of $Mg(BH_4)_2 \cdot 2NH_3$, the incorporation of $LiBH_4$ with the formation of $LiMg(BH_4)_3 \cdot 2NH_3$ slightly increased Bader charges of B atoms, meanwhile it decreased Bader charges of N atoms. $Mg(BH_4)_2 \cdot 2NH_3$ shows a low ammonia vacancy diffusion barrier, but relatively high ammonia vacancy formation energy, which lead to a low concentration of NH_3 vacancies and limit NH_3 transportation. In contrast to that of $Mg(BH_4)_2 \cdot 2NH_3$, $LiMg(BH_4)_3 \cdot 2NH_3$ has a relatively high ammonia vacancy formation energy and diffusion barrier, which suppresses ammonia release. The incorporation of $LiBH_4$ and $Mg(BH_4)_2 \cdot 2NH_3$ does not decrease but increases the hydrogen formation barrier of $LiMg(BH_4)_3 \cdot 2NH_3$, resulting in a slight increase in the dehydrogenation peak temperature, consistent with experimental results.

Introduction

Recently, many efforts have been devoted to B-N based chemical hydrides as potential hydrogen storage materials because of their high theoretical hydrogen capacity.¹⁻³ For instance, ammonia borane (AB), with a high H-capacity of 19.6 wt%, is a typical B-N based hydride for chemical hydrogen storage.1 However, upon decomposition of AB, accompanied volatile compounds of ammonia, diborane, and borazine are evolved, which lead to a reduction of dehydrogenation capacity and are fatal for fuel cell applications.1,4 Many different approaches have been adopted to facilitate hydrogen release from AB during the last decade.5-10 Recent studies show that the substitution of H atoms in the NH3 unit of AB by alkali metals with the formation of single or double metal amidoborane (MAB) is an effective way to improve the dehydrogenation properties of AB in terms of the reduced H₂ release temperatures, accelerated H₂ release kinetics, and minimized borazine evolved. 5,6,11-17

Ammine metal borohydrides (AMBs), which show favourable hydrogen storage properties competitive with ammonia borane, have been developed recently as promising materials for hydrogen storage.¹⁸⁻³¹ However, many of these composites suffer from the release of undesirable gas of ammonia during

theory (DFT) calculation.

dehydrogenation. Further experimental results show that the

purity of gas released and dehydrogenation temperature of AMBs can be improved by using double-cation substitutions

approach and tuning BH₄/NH₃ ration. ^{15,24,32,33} The experimental

and theoretic studies indicate that ammonia is weakly bound to the metal cations with low electronegativity (<1.2) in AMBs,

therefore tend to release ammonia at low temperature. 32,34

Although these studies have provided valuable insight for

understanding the decomposition processes of single metal

cation AMBs, the results may not be applicable to double

cations AMBs. For instance, $Mg(BH_4)_2 \cdot 2NH_3$ (with electronegativity of 1.31 for Mg cation) mainly release hydrogen along with

a small amount of ammonia.23 The incorporation of LiBH4 (with

low electronegativity of 0.98 for Li cation) and $Mg(BH_4)_2 \cdot 2NH_3$ with the formation of double cations ammine borohydride,

LiMg(BH₄)₃·2NH₃ results in improving the purity of gas released compared to Mg(BH₄)₂·2NH₃.³⁵ Further improved

dehydrogenation of ammine magnesium borohydride by tuning

the NH₃/BH₄ ratios and combining Mg(BH₄)₂·2NH₃ with MgH₂ and NaAlH₄ were reported.³⁶⁻³⁹

The mixed-cation strategy offers a promising route toward tuneable dehydrogenation of ammine metal borohydrides, however, a detail study of the dehydrogenation mechanism is still needed for further improving their dehydrogenation performance. Herein, we presented a comparison study of the electronic structure and dehydrogenation mechanisms of Mg(BH₄)₂·2NH₃ and LiMg(BH₄)₃·2NH₃ by density functional

Computational method

Mg(BH₄)₂·2NH₃ crystallizes in the orthorhombic structure with space group of *Pcab* and lattice parameters of a = 17.4872(4) Å, $b = 9.4132(2) \text{ Å, } c = 8.7304(2) \text{ Å.}^{23} \text{ LiMg}(BH_4)_3 \cdot 2NH_3 \text{ has}$ a hexagonal structure with space group P63 and lattice constants of a = b = 8.0002(1) Å and $c = 8.3944 \text{ Å}.^{35}$ The geometric structures were optimized by DFT calculation as implemented in MedeA@VASP code.40 To describe the weak van der Waals H⁺···-H dihydrogen bonds, the optB86b-vdW functional41-43 was adopted for geometric optimization. Plane waves with kinetic energy cutoff of 500 eV were used. The generalized gradient approximation (GGA) of Perdew-Burke-Ernzerhof (PBE) was adapted to treat the exchange and correlation of electronics.44,45 The projector-augmented wave (PAW) approach was used to describe the electron-ion interactions⁴⁶ with 1s2s2p of Li, s2p1 of B, s2p3 of N, s2p0 of Mg as the explicit valence electrons. The Brillouin zones were sampled by Monkhorst-Pack k-point meshes⁴⁷ with meshes points spacing less than 0.05 per Å for both $Mg(BH_4)_2 \cdot 2NH_3$ and $LiMg(BH_4)_3 \cdot 2NH_3$. Structural relaxations of atomic positions were carried out until the total energies and residual forces were less than 1.0 \times 10^{-5} eV and 0.02 eV \mathring{A}^{-1} , respectively. For the calculation of NH₃ vacancy formation energies and H_2 formation energies, $1 \times 2 \times 1$ 2 supercells of Mg(BH₄)₂·2NH₃ and 2 \times 2 \times 2 supercells of $LiMg(BH_4)_3 \cdot 2NH_3$ were used. Our tests showed that the used of $1 \times 2 \times 2$ supercells of Mg(BH₄)₂·2NH₃ and $2 \times 2 \times 2$ supercells of $LiMg(BH_4)_3 \cdot 2NH_3$ with k-point mesh spacing less than 0.05 per Å yield energies that converged within 0.01 eV $(f.u.)^{-1}$. The NH₃ diffusion barriers and H₂ formation barriers were estimated by using climbing image nudged elastic band (CI-NEB) method.48,49

The NH₃ vacancy formation energy was estimated using the following equation:

$$E_{\rm c} = E_{\rm total} - E({\rm AMBs-NH_3}) - E({\rm NH_3})$$

where E_{total} is the total energy of the AMBs supercells; $E(\text{NH}_3)$ represents the energy of isolate NH₃ molecule; $E(\text{AMBs-NH}_3)$ is

the total energy of the AMBs supercells after NH_3 molecules are removed. The positive energy of E_c indicates that the creation of NH_3 vacancy is an endothermic process; while the negative energy of E_c indicates that the creation of NH_3 vacancy is an exothermic process.

The concentration of ammonia vacancy in $Mg(BH_4)_2 \cdot 2NH_3$ and $LiMg(BH_4)_3 \cdot 2NH_3$ could be estimated by the following equation⁵⁰

$$c = N_{\text{sites}} N_{\text{config}} \exp(E_{\text{c}}/kT)$$

where $E_{\rm c}$ is the formation energy of NH₃ vacancy; $N_{\rm sites}$ represents the number of sites that the defect can be incorporated; $N_{\rm config}$ is the number of configurations per site in which the vacancy can be formed; k and T represent Boltzmann constant and temperature, respectively.

Results and discussion

Electronic structure

The electron localization function (ELF) and charge transfer between the H, N, B atoms and metal cations (Li and Mg) were analysed to understand the bonding characters of Mg(BH₄)₂- \cdot 2NH₃ and LiMg(BH₄)₃ \cdot 2NH₃. The H atoms bond to N atom and B atom are represent as (N)H and (B)H, respectively. As shown in Fig. 1, the calculated ELF shows the covalent bonding of N-H and B-H. Although the Mg-H bonds are mainly ionic, the distorted ELF isosurfaces around (B)H, (N)H and Mg indicate partial covalent bond feature of Mg-H. The low ELF value around Li indicates the essentially ionic bonding character of Li-H. Table 1 shows the Bader charges of (B)H, N(H), N, B and Mg for Mg(BH₄)₂·2NH₃ are -0.58/-0.64, 0.44, -1.30, 1.59 and 1.65, respectively. The Bader charge of Li is 0.90 for $LiMg(BH_4)_3 \cdot 2NH_3$, indicates a strong ionization of the Li cation. Hence, Li cation transfers most of its 2s electron to neighbouring BH₄ unit, similar to that of LiBH₄. Compared to $Mg(BH_4)_2 \cdot 2NH_3$, the incorporation of LiBH₄ with the formation of LiMg(BH₄)₃·2NH₃ barely affects the charge distribution of H

and Mg. The Bader charge of B is slightly increased and Bader charge of N is slightly decreased in $LiMg(BH_4)_3 \cdot 2NH_3$.

Ammonia vacancy formation energies and diffusion barriers

As demonstrated by previous report, Mg(BH₄)₂·2NH₃ started to release hydrogen at temperature around 120 °C, with a maximum hydrogen release rate at 205 °C.²³ A small amount of NH₃ was released along with hydrogen evolution from Mg(BH₄)₂·2NH₃. The LiMg(BH₄)₃·2NH₃ shows dehydrogenation performance comparable to that of Mg(BH₄)₂·2NH₃, with dehydrogenation peak located at 221 °C.³⁵ In addition, incorporation of LiBH₄ with Mg(BH₄)₂·2NH₃ suppresses ammonia release.

The formation and transport properties of NH_3 vacancy are crucial to the thermodynamics and kinetics of ammonia release from AMBs. To understand the microscopic mechanisms behind the release of ammonia, the formation and diffusivity of NH_3 were studied. The NH_3 vacancy was created by directly removed a NH_3 unit from $Mg(BH_4)_2 \cdot 2NH_3$ and $LiMg(BH_4)_3 \cdot 2NH_3$.

As shown in Table 2, the calculated NH $_3$ removal energies are 1.81 and 1.97 eV for Mg(BH $_4$) $_2 \cdot$ 2NH $_3$ and LiMg(BH $_4$) $_3 \cdot$ 2NH $_3$, respectively. The relatively high NH $_3$ removal energies indicates that the formation of NH $_3$ vacancies are thermodynamics unfavourable at low temperature, resulting in low concentration of ammonia vacancy for those two composites. The high formation energy of NH $_3$ vacancies can attribute to the coordination bond of Mg–N and H $^+ \cdot \cdot \cdot$ H dihydrogen network.

In addition to the formation energies of NH_3 vacancies, the diffusive of NH_3 vacancies is also importance for ammonia release. The diffusion paths were calculated by moving a NH_3 unit from a nearby lattice site into the vacancy. The diffusion barrier is defined as the energy difference between the saddle point and the ground state. The activation energy (Q) for self-diffusion of ammonia can be obtained by combining the

Table 2 Calculated NH₃ vacancy formation energies (E_c), diffusion barriers (E_b) and activation energies ($Q = E_b + E_c$) for Mg(BH₄)₂·2NH₃ and LiMg(BH₄)₃·2NH₃

| | $E_{\rm c}$ (eV) | $E_{\rm b}$ (eV) | Q (eV) |
|----------------------------|------------------|------------------|--------|
| $Mg(BH_4)_2 \cdot 2NH_3$ | 1.81 | 0.26 | 2.07 |
| $LiMg(BH_4)_3 \cdot 2NH_3$ | 1.97 | 1.31 | 3.28 |

calculated vacancy formation energy with the diffusion barrier. As summarized in Fig. 2 and Table 2, for $Mg(BH_4)_2 \cdot 2NH_3$, the calculated energy barrier and activation energy of ammonia diffusion are 0.26 and 2.07 eV, respectively. It should be noted that the NH_3 diffusion barrier is relatively low, the formation energy of NH_3 vacancy is the dominate term in the activation energy for ammonia diffusion. The relatively high formation energy would result in low concentration of NH_3 vacancy, which limit its transport in $Mg(BH_4)_2 \cdot 2NH_3$. This is in agreement with previous report that only a small amount of NH_3 was released during decomposition of $Mg(BH_4)_2 \cdot 2NH_3$.²³

The calculated ammonia vacancy diffusion barrier and activation energy of LiMg(BH₄)₃·2NH₃ are 1.31 and 3.28 eV, respectively. Compared to that of Mg(BH₄)₂·2NH₃, the relatively high ammonia diffusion barrier and activation energy indicate that low concentration and mobility of ammonia vacancy in LiMg(BH₄)₃·2NH₃, in inconsistent with experimental results that the dehydrogenation purity of Mg(BH₄)₂·2NH₃ can be improved by introducing LiBH₄ with the formation of LiMg(BH₄)₃·2NH₃.³⁵

Hydrogen formation energies and barriers

Our previous studies suggest that the initial dehydrogenation of AMBs is achieved by combination of H atoms from NH3 and H atoms from BH₄ groups. 51,52 Therefore, H₂ formation energies were calculated by moving one (N)H and one (B)H atom away from host N or B atom to form a hydrogen molecule with H-H distance of 0.74 Å in the supercell of AMBs. The geometry optimization was first performed by fixed the H₂ positions and relaxed the rest of the atoms, following by full relaxed all of the atoms in the supercell. In agreement with our previous studies, the formation of H₂ molecules lead to significant rearrangement of the surrounding lattice, which may result in overestimated the hydrogen formation energies. In addition, both $Mg(BH_4)_2 \cdot 2NH_3$ and $LiMg(BH_4)_3 \cdot 2NH_3$ started to release hydrogen at temperature higher than their melting point. In other word, the crystal structure of Mg(BH₄)₂·2NH₃ and LiMg(BH₄)₃·2NH₃ disappeared before hydrogen evolved. Therefore, we further calculated the hydrogen formation energies by using the molecule model in which two formula units of $Mg(BH_4)_2 \cdot 2NH_3$ and $LiMg(BH_4)_3 \cdot 2NH_3$ were placed in a cubic cell with lattice parameter of 20 Å.

As shown in Table 3, the calculated hydrogen formation energies by using supercell of AMBs are 0.84 and 1.22 eV for Mg(BH₄)₂·2NH₃ and LiMg(BH₄)₃·2NH₃, respectively. In consistent with our previous theoretical study, the dissociation of H₂ results in dramatic movement of around atoms.⁵¹ The hydrogen formation energies calculated by molecule model are -0.11 and 0.08 eV for Mg(BH₄)₂·2NH₃ and LiMg(BH₄)₃·2NH₃, respectively. The combination of the (N)H and (B)H results in rearrangement of the surrounding atoms, similar with our previous report.⁵¹ The NH₂ and BH₃ units reoriented and BH₃ units moved toward NH₂ to form NH₂-BH₃ complexes. The N-B distances reduce to 1.58 Å, indicating the formation of N-B bond during dehydrogenation, in agreement with experimental observation.^{14,35} However, the lengths of Li-

Table 3 Formation energies of H₂ release via (N)H and (B)H combination by using crystal model (E_{H_2-C}) and molecule model (E_{H_2-M})

| | $E_{\mathrm{H_2-C}}$ (eV) | $E_{\mathrm{H_2-M}}$ (eV) |
|-----------------------------------------------------|---------------------------|---------------------------|
| $Mg(BH_4)_2 \cdot 2NH_3$ $LiMg(BH_4)_3 \cdot 2NH_3$ | 0.84 1.22 | -0.11 0.08 |

N, Mg-N, B-H and N-H bonds keep almost the same after structural rearrangements.

The low H₂ formation energies of Mg(BH₄)₂·2NH₃ and LiMg(BH₄)₃·2NH₃ suggest that the formation of hydrogen is thermodynamic favourable at low temperature. Therefore, the energy barrier of H2 formation is the key of those two composites release hydrogen at temperature above 100 °C.

We further calculated the energy barriers of H2 formation and the results were summarized in Fig. 3. The calculated energy barrier of H₂ formation from Mg(BH₄)₂·2NH₃ is 2.20 eV. The transition geometric structure of hydrogen release from Mg(BH₄)₂·2NH₃ (Fig. 3(a)) shows the broken of B-H and N-H bonds with the formation of H₂ molecule. The H₂ molecule is located between NH2 and BH3 units with H2-NH2 and H2-BH3 distances of 2.47 and 2.31 Å, respectively. Meanwhile, the NH₂ unit move toward Mg cation and lead to slightly reduce the Mg-N distance from 2.16 to 1.95 Å. The calculated hydrogen formation energy barrier of LiMg(BH₄)₃·2NH₃ is 2.55 eV, which is 0.35 eV higher than that of Mg(BH₄)₂·2NH₃. Previous experimental results show dehydrogenation peak of 205 °C and

221 °C for Mg(BH₄)₂·2NH₃ and LiMg(BH₄)₃·2NH₃, respectively. 23,35 The relatively high dehydrogenation peak of LiMg(BH₄)₃·2NH₃ can be attributed to the high hydrogen formation barrier. The transition geometric structure of hydrogen release from LiMg(BH₄)₃·2NH₃ is similar to that of $Mg(BH_4)_2 \cdot 2NH_3$. The H_2 molecule is located between NH_2 and BH₃ unit. The H₂-NH₂ distance in transition structure of $LiMg(BH_4)_3 \cdot 2NH_3$ is 2.24 Å, which is 0.23 Å shorter than that in Mg(BH₄)₂·2NH₃. And the H₂-BH₃ distance in transition structure of LiMg(BH₄)₃·2NH₃ is 2.11 Å, which is 0.20 Å shorter than that in $Mg(BH_4)_2 \cdot 2NH_3$. In addition, the NH_2 unit shortening its distance to the Mg cation from 2.19 to 1.95 Å, similar to that of $Mg(BH_4)_2 \cdot 2NH_3$.

Although the above calculations show a low NH3 diffusion barrier for Mg(BH₄)₂·2NH₃, the formation energy of NH₃ vacancy is relatively high, which results in low concentration of NH₃ vacancy in Mg(BH₄)₂ · 2NH₃. Therefore, the Mg(BH₄)₂ · 2NH₃ mainly releases hydrogen accompany with a small amount of ammonia during decomposition. In contrast to that of $Mg(BH_4)_2 \cdot 2NH_3$, LiMg(BH₄)₃ · 2NH₃ shows relatively high formation energy and diffusion barrier of NH3 vacancy, which limit both the concentration and transport of ammonia, therefore improve the dehydrogenation purity. The calculated hydrogen formation barrier of LiMg(BH₄)₃·2NH₃ is slightly higher than that of $Mg(BH_4)_2 \cdot 2NH_3$, therefore incorporation of LiBH₄ with Mg(BH₄)₂·2NH₃ may not decrease the dehydrogenation temperature.

Paper

Fig. 3 The calculated energetic profiles, initial (IS), transition (TS) and final (FS) geometric structure of H_2 formation for (a) $Mg(BH_4)_2 \cdot 2NH_3$ and (b) LiMg(BH₄)₂·2NH₃. E_b represents the calculated energy barrier. The green, pink, orange, purple and blue colours represent B, H, Mg, Li and N atoms, respectively.

Conclusions

First-principles calculations based on density functional theory were carried out to investigate the decomposition mechanisms of $Mg(BH_4)_2 \cdot 2NH_3$ and $LiMg(BH_4)_3 \cdot 2NH_3$. The electronic structure analysis indicates that Mg-H interaction in those two composites are mainly ionic with partial covalent bond feature. The incorporation of LiBH₄ and Mg(BH₄)₂·2NH₃ with the formation of LiMg(BH₄)₃·2NH₃ barely affects the charge distribution of H and Mg. The Bader charge of B is slightly increased and Bader charge of N decreased due to the incorporation of LiBH₄. Although the NH₃ diffusion barrier for Mg(BH₄)₂·2NH₃ is low, the relatively high formation energy of NH₃ vacancy lead to low concentration of NH₃ vacancy and limit its transportation, in agreement with experimental results that Mg(BH₄)₂·2NH₃ mainly releases hydrogen along with a small amount of ammonia. The LiMg(BH₄)₃·2NH₃ shows relatively high ammonia vacancy formation energy and diffusion barrier, which suppress ammonia release compared to $Mg(BH_4)_2 \cdot 2NH_3$. The incorporation of LiBH₄ and Mg(BH₄)₂·2NH₃ does not decrease the hydrogen formation barriers, instead slightly increase the hydrogen formation barriers of LiMg(BH₄)₃·2NH₃, in agreement with experimental results that LiMg(BH₄)₃·2NH₃ shows a dehydrogenation peak slightly higher than that of $Mg(BH_4)_2 \cdot 2NH_3$.
