Incorporating a TiO$_x$ shell in single-walled carbon nanotube/fullerodendron coaxial nanowires: increasing the photocatalytic evolution of H$_2$ from water under irradiation with visible light†

K. Kurniawan, T. Tajima, Y. Kubo, H. Miyake, W. Kurashige, Y. Negishi and Y. Takaguchi

A custom-tailored single-walled carbon nanotube (SWCNT) photocatalyst with an electron-extracting TiO$_x$ shell, i.e., a SWCNT/fullerodendron/TiO$_x$ coaxial nanowire, has been fabricated. Due to the presence of the TiO$_x$ shell, the SWCNT/fullerodendron/TiO$_x$ coaxial nanowire shows an enhanced photocatalytic activity ($\Phi = 0.47$) for the evolution of hydrogen from water under irradiation with visible light ($\lambda = 450$ nm).

The interfaces between metal oxides and organic compounds play an important role in the field of organic electronics, which include organic light-emitting devices (OLEDs), organic photovoltaic cells (OPVs), dye-sensitized solar cells (DSSCs), and transistors. To improve the device performance, these interfaces can often be modified by insertion of a functional interfacial layer. For example, transparent titanium oxides (TiO$_x$) exhibit electronic levels that match the LUMOs of the C$_{60}$-derivatives used in OPVs well, which renders TiO$_x$ a promising candidate for electron-transport materials. Waldauf and co-workers have prepared OPVs with an ITO/TiO$_x$/RR-P3HT:PCBM/PEDOT:PSS/Au structure using coating techniques, and demonstrated that these OPVs exhibit improved fill factors (FF). Kuwabara et al. have reported efficient inverted BHJ solar cells that contain TiO$_x$ as the electron-extraction layer, which resulted in an improved short-circuit photocurrent ($I_{sc}$), open-circuit voltage ($V_{oc}$), FF, and power-conversion efficiency ($\eta$).

Meanwhile, coaxial nanowires with a donor–acceptor heterojunction have shown great potential for applications in innovative photofunctional materials. Recent theoretical and experimental studies have indicated that coaxial nanowire structures could potentially improve the carrier collection and overall efficiency relative to bulk semiconductors of the same materials. We have reported the fabrication and efficient photo-induced electron-transfer processes of single-walled carbon nanotube (SWCNT)/anthryl dendron and SWCNT/fullerodendron supramolecular nanocomposites, wherein a coaxial nanowire structure provides a donor–acceptor heterojunction between the SWCNT-core and the C$_{60}$-based fullerodendrons. We have also shown that SWCNT/fullerodendron ($\Phi = 0.28$) and SWCNT/fullerodendron/SiO$_2$ ($\Phi = 0.31$) coaxial nanohybrid materials can be used as effective photosensitizers for the catalytic evolution of H$_2$ from water under irradiation with visible light ($\lambda = 450$ nm). Moreover, we have reported the direct incorporation of a co-catalyst into the shell of SWCNT/fullerodendron supramolecular nano-composites.

Upon chirality-selective photo-excitation using monochromatic light ($\lambda = 680$ nm), which is suitable for the $E_{22}$ absorption of (8,3) SWCNTs, we observed the first example for the evolution of H$_2$ ($\Phi = 0.015$) photosensitized by SWCNTs. However, further improvements of the quantum yield of the SWCNT photocatalyst are necessary in order to further develop this technology.

These results prompt us to explore a new coaxial photosensitizer with a TiO$_x$ shell as an electron-extraction layer that covers a photo-functional SWCNTs/C$_{60}$ interface. Here we describe the fabrication of SWCNT/fullerodendron/TiO$_x$ coaxial nano-hybrids that can be used for the effective photo-catalytical evolution of H$_2$, which shows the highest AQYs ($\Phi = 0.47$) under irradiation with visible light ($\lambda = 450$ nm).

The molecular structure of the fullerodendron used in the present study is shown in Fig. 1. SWCNT/fullerodendron/TiO$_x$ nano-hybrids were fabricated by a polycondensation reaction of titanium tetra isopropoxide (TTIP) using SWCNT/fullerodendron supramolecular nano-composites (Fig. 1) as catalytic scaffolds according to previous reports on SWCNT/fullerodendron/SiO$_2$ nano-hybrids. In a typical run, an aqueous solution of SWCNT/fullerodendron nanocomposites...
solution of titanium tetra isopropoxide (3.51 mM, pH 3 with HCl (1.0 N, 2.8 mol/L)) was added to the solution at 0°C. After the stirring for 1 h, an EtOH solution of titanium tetra isopropoxide (3.51 mM, 20 μL, 7.4 × 10⁻⁸ mol) was added to the solution at 0°C and stirred for 48 h to obtain a dispersion of SWCNT/fullerodendron/TiO₂ coaxial nano-hybrids.

The morphology of the SWCNT/fullerodendron/TiO₂ nano-hybrids was examined by scanning electron microscopy (SEM). The SEM images exhibited SWCNT/fullerodendron/TiO₂ nanowires that are similar to SWCNT/fullerodendron/SiO₂ nanowires (Fig. 2). This structural observation is consistent with the results of transmission electron microscopy (TEM; Fig. S1†) and atomic force microscopy (AFM) measurements (Fig. S2†). The TEM analysis indicated that a uniformly thick shell composed of nano-sized TiO₂ covered the SWCNT/fullerodendron nano-wire. The height profiles in the AFM analysis revealed that the thickness of SWCNT/fullerodendron/TiO₂ coaxial nano-hybrids (~15 nm) is higher than that of the SWCNT/fullerodendron supramolecular nano-composite (2–3 nm). Based on these results, the thickness of the TiO₂ layer was estimated to be 6–7 nm. These observations are consistent with the SWCNT/fullerodendron/TiO₂ coaxial nano-hybrid structure, the SWCNT-core surrounded by the fullerodendrons, coated by the outer TiO₂ shell.

A Raman spectrum of the SWCNT/fullerodendron/TiO₂ coaxial nano-hybrids showed typical scattering of the disorder-induced mode (D) and the tangential displacement mode (TDM; also called the G band), which were observed at 1339 and 1610 cm⁻¹, respectively (Fig. S3†). The very small intensity of the D-band indicates that the SWCNTs within the composites did not sustain any substantial damage. Broad peaks at 610 and 425 cm⁻¹ were ascribed to TiO₂. To obtain a better understanding of the fullerodendron/TiO₂ junction, FT-IR spectroscopic measurements of the SWCNT/fullerodendron/TiO₂ nano-hybrid were conducted (Fig. S4†). The IR spectra of the SWCNT/fullerodendron/TiO₂ nano-hybrids exhibit the C=O stretching modes at 1725 cm⁻¹, which is shifted toward higher frequencies than those of the SWCNT/fullerodendron supramolecular nano-composites (1680 cm⁻¹). This result indicates the formation of Ti–OCOR bonds¹⁰ at the termini of the fullerodendrons. The sharp absorption band observed at 635 cm⁻¹ was ascribed to the Ti–O–Ti moieties, while the strong absorption band at 1055 cm⁻¹ was attributed to the Ti–O–C stretching mode. Based on these observations, we concluded that the TiO₂ layer is attached onto the surface of the SWCNT/fullerodendron supramolecular nano-composites without significant damage to the SWCNTs.

The TiO₂ layer of the SWCNT/fullerodendron/TiO₂ nano-hybrids shows high optical transparency in the visible and near infrared (NIR) region. Fig. 3a and S5† show the absorption spectra of the SWCNT/fullerodendron supramolecular nano-composites and the SWCNT/fullerodendron/TiO₂ coaxial nano-hybrids. The absorption of the SWCNT/fullerodendron/TiO₂ coaxial nano-hybrids is smaller than that of the SWCNT/fullerodendron composites, as the concentration of the SWCNT/fullerodendron/TiO₂ coaxial nano-hybrids was lowered during the sol–gel condensation process. However, the absorption and/or scattering due to the TiO₂ layer on the shell should be negligible on account of the nano-sized thickness of the TiO₂ layer. The coaxial nanowire structure with isolated SWCNTs was confirmed by three-dimensional photoluminescence (PL) intensity mapping in D₂O (Fig. 3b), which allowed assigning four intense peaks with reasonable certainty to the (9,4), (8,6), (7,6), and (8,4) SWCNTs. It should be noted that the coaxial structure is maintained, i.e., the formation of bundles and/or aggregation of the SWCNTs after the formation of the SWCNT/fullerodendron/TiO₂ coaxial nano-hybrids was not observed.

To probe the beneficial aspects of the incorporation of the transparent electron-extraction layer into an SWCNT/fullerodendron coaxial photosensitizer, we explored the photocatalytic evolution of H₂ from water using a system based on the SWCNT/fullerodendron/TiO₂ supramolecular nano-composites coupled with colloidal poly(vinylpyrrolidone)–platinum (PVP–Pt). Typically, 150 mL of an aqueous solution,
consisting of SWCNT/fullerodendron/TiO₂ nano-composites (1 mL), Tris–HCl buffer (3.5 mL in H₂O, pH 7.5, 5 mM), methyl viologen dichloride (MV; 92.4 mg, 359 μmol), 1-benzyl-1,4-dihydronicotinamide (BNAH; 38.6 mg, 180 μmol), and a colloidal solution of PVP–Pt (15 mL in H₂O; 512 μmol of Pt), was vigorously stirred at 25 °C while being exposed to light (λ > 422 nm) from a 300 W Xe arc lamp. After the designated period, the gas phase above the solution was analyzed by gas chromatography. Fig. 4 shows the plots of the total amount of H₂ produced as a function of time using either SWCNT/fullerodendron/TiO₂ coaxial nano-hybrids (●) or SWCNT/fullerodendron composites (▲). The generation of H₂ (4.0 μmol h⁻¹) proceeded steadily and an induction period or decreasing activity was not observed during 6 h of irradiation.

Although the SWCNT/fullerodendron supramolecular nano-composites also worked as a photosensitizer for the evolution of H₂, the reaction rate of the H₂ generation (1.9 μmol h⁻¹; Fig. 3) is lower than that of SWCNT/fullerodendron/TiO₂ nano-hybrids (4.0 μmol h⁻¹). Given that the absorbance of the SWCNT/fullerodendron/TiO₂ nano-hybrids is lower than that of the SWCNT/fullerodendron supramolecular nano-composites, the photocatalytic activity of the SWCNT/fullerodendron/TiO₂ nano-hybrids must be higher than that of the SWCNT/fullerodendron supramolecular nano-composites. In order to compare the efficiency of the photocatalytic evolution of H₂ between the SWCNT/fullerodendron supramolecular nano-composite and the SWCNT/fullerodendron/TiO₂ nano-hybrid photocatalysts, we evaluated their quantum yields by using monochromatic light (λ = 450 ± 2 nm), which revealed apparent quantum yields (AQYs) for the evolution of H₂ (2 × number of molecules of H₂ generated/number of photons absorbed) of 0.47 (SWCNT/fullerodendron/TiO₂) and 0.12 (SWCNT/fullerodendron). By changing the reaction time of sol–gel condensation, it seems that we can control the thickness of TiO₂ layer on the SWCNT/fullerodendron supramolecular nano-composites as judged by the SEM images (Fig. S6†). The photocatalytic activity of SWCNT/fullerodendron/TiO₂ nano-hybrids is affected by the reaction time of sol–gel condensation. The reaction rate of the H₂ generation were 0.1 μmol h⁻¹ (for 1 day condensation), 4.0 μmol h⁻¹ (for 2 day condensation), and 0.1 μmol h⁻¹ (for 3 day condensation), respectively. The SWCNT/fullerodendron/TiO₂ nano-hybrids maintained its photocatalytic activity for at least 12 h. However, the H₂ production rate gradually decreases along with irradiation. The result can be attributed to the decrease of BNAH (sacrificial electron donor) concentration. It is notable that 81% of H₂-evolving activity was remained for the second use of a spray-coated film of SWCNT/fullerodendron/TiO₂ on a FTO plate after the 6 hour H₂ evolution reaction upon illumination followed by the rinsing and drying.

An energy-level diagram of the conduction (C₁ and C₂) and valence bands (V₁ and V₂) of (7,6) SWCNT, which is one of the most commonly encountered types of CNTs in HiPco, together with the LUMO levels of C₆₀, MV²⁺, BNAH, and the energy level of Pt and TiO₂ is shown in Fig. 5. A distinctive advantage of the coaxial architecture is that the carrier separation occurs in the shorter radial direction as opposed to the longer axial direction. Moreover, the energy-level diagram indicates that the electron-extraction layer of TiO₂ not only decelerates the electron back-transfer, but also accelerates the electron forward-transfer from the conduction band of TiO₂ to the LUMO of MV²⁺, thus leading to an efficient electron-transfer pathway.
A bespoke SWCNT photocatalyst with an electron-extracting TiO$_2$ shell was fabricated. On account of the presence of the TiO$_2$ shell, the SWCNT/fullerodendron/TiO$_2$ coaxial nanowire exhibits a high activity in the catalytic evolution of H$_2$ from water under irradiation with visible light, because the electron-extracting TiO$_2$ layer accelerates the electron forward-transfer under concomitant deceleration of the undesirable electron back-transfer. Even though various kinds of organic and inorganic coaxial nanowires have been developed so far, coaxial nanowire photocatalysts consisting of (p-type semiconductor)/(n-type semiconductor)/(electron-extraction layer) are still in the early stages of development, mostly due to their relatively complicated fabrication procedures. Further studies on the applications of such SWCNT photocatalysts with coaxial nanowire structures are currently in progress, and will be reported in due course.
