Manganese dioxide core–shell nanostructure to achieve excellent cycling stability for asymmetric supercapacitor applications

Quanbing Liu, Juan Yang, Rongfang Wang, Hui Wang and Shan Ji

This study presents a facile and low-cost method to prepare core–shell nano-structured β-MnO2@δ-MnO2, in which β-MnO2 nano-wires act as the cores to form 3D networks and δ-MnO2 as the shells. A uniform hierarchical β-MnO2@δ-MnO2 core–shell structure can be obtained after layered structured δ-MnO2 is deposited on the surface of the needle-like β-MnO2 particles via a simple wet chemistry method at room temperature. The as-prepared materials were physically and electrochemically characterized by nitrogen isotherm analysis, X-ray diffraction, scanning electron microscopy, transmission electron microscopy and potentiostatically/galvanostatically. Under our conditions, the electrochemical results showed that the specific capacitance of β-MnO2@δ-MnO2 was ~200 F g⁻¹ and the specific capacitance retention was almost 100% after 5000 cycles at a current density of 1 A g⁻¹ in 1 M LiOH electrolyte. The excellent cycling stability of β-MnO2@δ-MnO2 showed that the new material has great potential for use in electrochemical supercapacitors, and the facile wet chemistry method used to synthesize β-MnO2@δ-MnO2 could be a promising method to produce highly stable MnO2-based electrode materials in large batches.

1. Introduction

High-performance supercapacitors have received enormous interest as promising Energy Storage Devices (ESDs) for mobile electronics, backup power supplies and electric vehicles due to their high power density, fast charge/discharge capability and long cycle life.¹–⁴ Electrochemical supercapacitors using MnO₂ as electrode materials have attracted significant attention; this is due to the fact that they possess high theoretical capacitance, large electrode potential window, and are low-cost, non-toxic and environmentally benign in comparison to those using ruthenium oxides or other transition metal oxide electrodes.⁵–⁸ MnO₂ of various crystallographic polymorphs (such as α-, β-, δ-, γ- and ε-MnO₂) consist of MnO₆ units in which each Mn⁴⁺ is surrounded by six oxygen atoms.⁹ It was found that polymorphs consisting of MnO₆ octahedra are interlinked yielding various structures with different tunnels or interlayers.¹⁰ Moreover, the charge storage in transition metal oxides is a multi-step process involving electrolyte ion transfer on the interface of the electrode/electrolyte and the intercalation/deintercalation of cations. Recent studies showed that materials possessing two-dimensional (2D) layered structure and wide interlayer spacing are ideal electrode materials for electrochemical supercapacitors, providing promising features, e.g. favouring the transport of electrolyte ions and the intercalation/deintercalation processes, leading to highly efficient ESDs.¹¹

The capacitance properties of MnO₂ strongly rely upon the intercalation/deintercalation of cations into or from its structure in aqueous electrolytes, indicating that structures with large size tunnels or interlayers result in better capacitance performance.¹² Among all these MnO₂ polymorphs, δ-MnO₂ with edge-shared MO₆ octahedra have shown to exhibit decent electrochemical performances, making it a promising electrode material for electrochemical supercapacitors.¹³–¹⁵ This is due to the fact that this polymorph is a two-dimensional layer-structured material with a relatively large interlayer distance (~7.0 Å). Recently, many studies have focused on routes and techniques for the preparation of δ-MnO₂. For example, Li et al. reported that δ-MnO₂ synthesized by a microwave-hydrothermal method under low pressure exhibited a specific capacitance of 210 F g⁻¹ at a current density of 200 mA g⁻¹ in a 1.0 M Na₂SO₄ electrolyte.¹⁶ Ji et al. deposited hierarchical δ-MnO₂ nano-sheets directly onto a nickel foam substrate using a one-pot chelation-mediated aqueous method, and the as-prepared material exhibited a relatively high capacitance of 325 F g⁻¹ at a current density of 1 A g⁻¹.¹⁷ Zhang et al. synthesized δ-MnO₂/holey graphene hybrid fibre by activating graphene fibre in a H₃PO₄ solution, followed by the deposition of δ-MnO₂ on its surface.¹⁸ The electrochemical results showed that the obtained material...
exhibited a large specific capacitance of 245 F g\(^{-1}\) at a current
density of 1 A g\(^{-1}\) in a 1 M Na\(_2\)SO\(_4\) solution. Although many
efforts have been devoted to the preparation of δ-MnO\(_2\) material
for electrochemical supercapacitors, it still remains a challenge
to obtain δ-MnO\(_2\) with good cycling capability and stability. This
is because (a) these 2D layered nano-structures often result in
low electronic properties due to the poor contacts between each
other and (b) their crystal structures are not stable under the
electrochemical reactions.\(^{17,18}\)

In order to improve the cycling stability and achieve better
electrochemical performance of δ-MnO\(_2\), an alternative and
promising way is to develop hierarchical structures using
different types of metal oxides. One-dimensional (1D) MnO\(_2\)
nano-sized materials can provide reliable electrical contact
between the 1D nano-sized MnO\(_2\) particles due to the formation
of the three-dimensional (3D) network.\(^{17}\) A hierarchical struc-
ture combining a 1D β-MnO\(_2\) with a 2D δ-MnO\(_2\) could result in
better electrochemical performances due to (a) the good elec-
trical conductivity of the 1D structure and (b) the high surface
area for ion adsorption on the 2D architecture improving the
diffusion of the charge carriers. Also, there are many rooms in
such hierarchical structure which can effectively buffer any
volume change during intercalation/deintercalation of
ions.\(^{19}\)

In this study, the authors present a facile and low-cost
approach for producing hierarchical core–shell structured
mixed phase manganese oxides, consisting of β-MnO\(_2\) nano-
wires acting as the core to form 3D networks and δ-MnO\(_2\)
covered on its surface as the shell. In this investigation, the
authors had for objective to produce a particle architecture that
combines layered structure δ-MnO\(_2\) supported on β-MnO\(_2\)
nano-wires. Through this unusual structural design, the ob-
tained core–shell structured manganese oxide exhibited both
high cycling stability and high electrochemical performance.

2. Experimental

2.1 Preparation of the samples

All reagents were of analytic grade (AR) and double-distilled
water was used all throughout the experiments. To prepare the
1D β-MnO\(_2\) nano-wires, 8 mmol of MnSO\(_4\) and 8 mmol of
(NH\(_4\))\(_2\)SO\(_4\) were added to 60 mL H\(_2\)O under intense stirring
(magnetic stirrer). Then this solution was transferred to a 100
mL Teflon-lined stainless-steel autoclave and heated at 120 \(^{\circ}\)C
for 12 h. The autoclave was cooled to room temperature, and the
product was filtered, washed with water and dried at 80 °C for 12 h. The resultant material was made of 1D β-MnO\(_2\) nano-
wires.

To prepare β-MnO\(_2\)@δ-MnO\(_2\), 60 mg of the as-prepared 1D β-
MnO\(_2\) nano-wires was added to 30 mL of 0.41 mmol MnSO\(_4\)
solution and ultrasonicated for 10 min using an ultrasonic bath
operating at 40 kHz. The obtained mixture was dropwise added
to 20 mL of 0.28 K\(_2\)MnO\(_4\) solution and then kept at room
temperature for 30 min. Then the product was collected (centrifuge), filtered, washed with water, and finally dried at
80 °C for 12 h. The obtained product was made of β-MnO\(_2\)@δ-
MnO\(_2\).

For comparison purposes, pure δ-MnO\(_2\) was also prepared
and the detail procedure is as follows: 30 mL of 0.41 mmol
MnSO\(_4\) was dropwise added to 20 mL of 0.28 K\(_2\)MnO\(_4\) solution.
The reaction was further allowed to proceed at room tempera-
ture for 30 min. The obtained pure δ-MnO\(_2\) was filtered, washed
with water and dried at 80 °C for 12 h.

2.2 Physical characterizations

XRD patterns were recorded on a Shimadzu XD-3A (Japan) using
filtered Cu-K\(_{\alpha}\) radiation (\(\lambda = 0.15418\) nm) generated at 40 kV
and at 30 mA. Scans for 2θ values were recorded at 4° min\(^{-1}\).
Scanning electron microscopy (SEM) images were obtained
using a Carl Zeiss Ultra Plus. Transmission electron microscopy
(TEM) high angle annular dark field scanning transmission
electron microscopy (STEM) images and selected area electron
diffraction (SAED) patterns of the catalysts were obtained using
a JEOL (JEM-2000 FX) microscope operating at 200 kV. Line-
scan energy dispersive spectroscopy (EDS) in the STEM mode
was used for elemental composition analysis. The sorption
isotherms were obtained on a Quantachrome Autosorb-1 vol-
metric analyzer. Specific surface areas were determined by the

2.3 Electrochemical characterizations

Cyclic voltammograms (CV) and galvanostatic charge/discharge
experiments on the as-prepared materials were carried out in
a three-electrode electrochemical cell. The working electrode
(WE) consisted of a film (1 cm\(^2\)) containing β-MnO\(_2\)@δ-MnO\(_2\)
(10 mg), carbon black and poly(tetrafluoroethylene) with a mass
ratio of 80 : 10 : 10, pressed into the Ni foam current collectors.
An Hg/HgO (1.0 M KOH) reference electrode (REF) and an
activated carbon counter electrode (CE) was used in all experi-
ments in 1 mol L\(^{-1}\) LiOH electrolyte. CV experiments were
performed on a CHI 650D electrochemical workstation. Galva-
nostatic charge/discharge tests were carried out on a Neware
Battery Tester (BTS6.0, Neware Technology Company, Guan-
dong, China).

3. Results and discussion

Fig. 1 shows the powder X-ray diffraction (XRD) patterns of β-
MnO\(_2\), δ-MnO\(_2\), and β-MnO\(_2\)@δ-MnO\(_2\). The XRD pattern of β-
MnO\(_2\) shows the typical peak dispersion indexed to β-MnO\(_2\)
tetragonal phase (Joint Committee on Powder Diffraction
Standards [JCPDS] Card 24-0735), in which no peaks related to
other types of MnO\(_2\) or amorphous MnO\(_2\) are observed, indicat-
ive of the formation of highly pure and crystalline β-MnO\(_2\).

The diffraction peaks of δ-MnO\(_2\), synthesized at room
temperature, are exhibited at angles of 37.2° and 67.2° which are
ascribed to (111) and (021) planes of δ-MnO\(_2\) [JCPDS Card: 42-
1317] respectively. However, these peaks are small and weak,
indicating that the as-prepared δ-MnO\(_2\) particles are small and
poorly crystalline. Similar XRD patterns of δ-MnO\(_2\) were also
found in the literature where the δ-MnO\(_2\) samples were
prepared at low temperature.\(^{15,20,21}\) In the case of β-MnO\(_2\)@δ-
MnO\(_2\), its XRD pattern shows no obvious difference from β-

MnO₂, for example the peaks resemble to those associated to a β-MnO₂ structure indicating that a small amount of δ-MnO₂ was formed on the surface of β-MnO₂.

Scanning electron microscope (SEM) and transmission electron microscope (TEM) images of β-MnO₂ and β-MnO₂@δ-MnO₂ are shown in Fig. 2(A), shows that the as-prepared β-MnO₂ particles are needle-like in shape and have a size of ca. 2–5 μm in length by direct statistic observation. The figure also shows that there is no presence of other forms of particles, indicating that highly pure β-MnO₂ with uniform morphology was formed, which is in very good agreement with the XRD results. SEM image of δ-MnO₂ is shown in Fig. 2(C), which comprise irregular particles and many particles aggregated into large particles. As shown in Fig. 2(B), a uniform hierarchical β-MnO₂@δ-MnO₂ core–shell structure was formed after the δ-MnO₂ was deposited on the surface of β-MnO₂ via the simple wet chemistry method at room temperature. From the figure, it can be seen that the δ-MnO₂ is hardly formed in the spaces between the β-MnO₂ nano-wires, implying that the formation of δ-MnO₂ preferentially occurs on the surface of β-MnO₂ nano-wires resulting in an uniform β-MnO₂@δ-MnO₂ core–shell structure. Fig. 2(E) shows a typical TEM image of β-MnO₂@δ-MnO₂. The figure shows that the β-MnO₂ has a uniform nano-wire structure with a diameter of ca. 70 nm. It can also be seen that δ-MnO₂ was uniformly distributed on the surface of β-MnO₂ nano-wires with a thickness of ca. 30 nm. However, there is no obvious evidence of boundaries between the β-MnO₂ core and δ-MnO₂ shell, showing that an intimate contact between these two different phases of MnO₂ exists. On the edge of the δ-MnO₂ shell, ultra-thin δ-MnO₂ nano-sheets are found and expected to provide improved electrochemical properties. Fig. 2(F) shows a detailed microstructure of the core and shell of β-MnO₂@δ-MnO₂, in which the atomic plane arrangement of δ-MnO₂ is clearly present, but with the absence of an atomic plane in the shell of δ-MnO₂. This finding further confirms that the δ-MnO₂ grown on the surface of β-MnO₂ is small and is of a poor crystalline structure. It is also observed that the δ-MnO₂ shell with layered structure was formed on the surface of β-MnO₂ nano-wires. Such a layered structure is expected to facilitate the intercalation/deintercalation of cations into and from the electrode materials resulting in an improved electrochemical capacitance performance.

The porous structures of β-MnO₂, δ-MnO₂ and β-MnO₂@δ-MnO₂ were evaluated by N₂ isotherm analysis (Fig. 3 and Table 1). The nitrogen adsorption–desorption isotherms of β-MnO₂ shows a type II isotherm (as defined by the International Union of Pure and Applied Chemistry (IUPAC)) with a sharp capillary condensation step at a relative high pressure (P/P₀ > 0.85). An hysteresis loop between adsorption and desorption curve could be considered as an H4-type, indicating a relatively large pore size, which could be due to the slit-shaped gap among the MnO₂ crystals. The isotherm of β-MnO₂@δ-MnO₂ also exhibits type II with a hysteresis loop at a high relative pressure, indicating that the as-prepared material is of a mesoporous nature. The isotherms of δ-MnO₂ is a mixed type in the IUPAC classification with a type I at a relative low pressure and a type II with an hysteresis loop at a relative intermediate and high pressure. At the initial part, there is an obvious uptake at a low relative pressure, which is a characteristic of a microporous structure. As shown in Fig. 3(B), the pore size distributions calculated from the Barrett–Joyner–Halenda (BJH) method show that the pore size distributions of δ-MnO₂ and β-MnO₂@δ-
MnO₂ are in the mesopore size range with a few micropores present. The BET surface area of δ-MnO₂ was found to be 248.91 m² g⁻¹, which is ~3 times higher than that of 1D β-MnO₂ (30.06 m² g⁻¹). After δ-MnO₂ was grown on the surface of needle-like 1D β-MnO₂, the BET surface area of β-MnO₂@δ-MnO₂ was determined to be 56.44 m² g⁻¹, which is almost twice as high as that of β-MnO₂, but still much lower than that of δ-MnO₂, due to the presence of a thin layer of δ-MnO₂ grown on β-MnO₂.

The electrochemical performance of the as-prepared β-MnO₂, δ-MnO₂ and β-MnO₂@δ-MnO₂ was evaluated by cyclic voltammetry (CV) and galvanostatic charge–discharge experiments in a three-electrode cell configuration and in 1 mol L⁻¹ LiOH electrolyte. Fig. 4(A) shows the CVs of the β-MnO₂, δ-MnO₂ and β-MnO₂@δ-MnO₂ electrodes at a scan rate of 5 mV s⁻¹ in 1.0 M LiOH solution and at room temperature. The figure shows that the CVs for the three samples exhibit a quasi-rectangular shape, typical of a pseudo-capacitive behaviour, with pairs of redox peaks corresponding to the reversible Faradaic redox reactions. The charge storage of MnO₂-based electrodes results from the adsorption/desorption and the intercalation/deintercalation of cations or protons of the electrolyte. The morphology, crystal structure and surface area play an important role in storing the charges. The current response on δ-MnO₂ is the highest among these three electrodes, suggesting that the high surface area and the layered structure favour the intercalation/deintercalation process as well as the adsorption/desorption occurring on the surface. On the β-MnO₂@δ-MnO₂ electrode, the current response is higher than that of the β-MnO₂ electrode, indicating additional capacitive contribution from δ-MnO₂ after it had been deposited on the surface of β-MnO₂. Fig. 4(C) and (D) show the CVs of β-MnO₂, δ-MnO₂ and β-MnO₂@δ-MnO₂ electrodes carried out over the potential range of ~0.15 to +0.60 V vs. Hg/HgO at various scan rates (5–100 mV s⁻¹). When the scan rate increases from 5 to 100 mV s⁻¹, the CVs of β-MnO₂ still retain a quasi-rectangular shape, even though the Faradaic process revolves around the electrochemical behaviour of β-MnO₂ in 1 M LiOH electrolyte, implying that the adsorption/desorption process dominates the charge storage process in β-MnO₂. In the case of δ-MnO₂ and β-MnO₂@δ-MnO₂, due to the layered structure of β-MnO₂, the Faradaic process contributed proportionately more to the charge storage than the electrical double-layer capacitance. Therefore, with increasing the scan rate, the CVs of δ-MnO₂ and β-MnO₂@δ-MnO₂ exhibit a distortion/change from quasi-rectangular shape due to electrode polarization. At fast scan rates, there is barely time for some Li⁺ ions to intercalate into the MnO₂ structure due to the polarization of the desolvation process of Li⁺ ions, resulting in the CVs deviating from the quasi-rectangular shape.

Fig. 5 shows the galvanostatic charge–discharge curves of the β-MnO₂, δ-MnO₂ and β-MnO₂@δ-MnO₂ at a current density of 50 mA g⁻¹. All three electrodes present non-linear charge curves, asymmetric to their corresponding discharge curves (as shown in Fig. 5(A)), which is commonly and typically observed for pseudo-capacitive materials. The charge–discharge curves exhibit a quasi-plateau over the potential range from +0.3 to +0.5 V vs. Hg/HgO. This quasi-plateau could originate from the intercalation/deintercalation of Li⁺ into or from MnO₂ structure which is consistent with the CV curves. The specific capacitance (Cₛ) values derived from the discharge curves were calculated using the following equation:

\[
c(F/g) = \frac{IΔt}{mΔV} \quad (1)
\]

Fig. 5 Galvanostatic charge–discharge curves of the β-MnO₂, δ-MnO₂ and β-MnO₂@δ-MnO₂ at a current density of 50 mA g⁻¹ (A), discharge curves of β-MnO₂ (B), β-MnO₂@δ-MnO₂ (C) and δ-MnO₂ (D) electrodes at various current densities.
where $I$ is the sampled current, $t$ is the sampling time span, $V$ is the total potential deviation of the potential window, and $m$ is the mass of the active electrode material. $C_s$ discharge values of $\beta$-MnO$_2$, $\delta$-MnO$_2$ and $\beta$-MnO$_2@\delta$-MnO$_2$ were found to be 100.3, 246.9 and 200.8 F g$^{-1}$ respectively. The increase in $C_s$ from the $\beta$-MnO$_2$ to $\delta$-MnO$_2$ indicates that the layered structure $\delta$-MnO$_2$ with high surface area contributed to $C_s$ in correlation with the CV results. Rate capability testing of $\beta$-MnO$_2$, $\delta$-MnO$_2$ and $\beta$-MnO$_2@\delta$-MnO$_2$ was evaluated at current densities ranging from 0.1 A g$^{-1}$ to 5 A g$^{-1}$ and the data are shown in Fig. 5(C and D). The results of rate capability experiments show that the specific capacitance decreased with increased current density, which is in good agreement with reported literature on MnO$_2$-based electrodes.\textsuperscript{4,26,27} When the current density increases from beyond 0.5 A g$^{-1}$, the quasi-plateau gradually disappears owing to the incomplete intercalation/deintercalation process.

The effect of the current density on the specific capacitance of $\beta$-MnO$_2$, $\delta$-MnO$_2$ and $\beta$-MnO$_2@\delta$-MnO$_2$ is shown in Fig. 6. It is clearly evident from the figure that the $C_s$ for all three samples gradually decreased when the current densities increased from 0.05 to 5 A g$^{-1}$. At the low current densities, all three electrodes show relatively high capacitance since the electrolyte ions have enough time to move to the interface of the electrode/electrolyte and take part to the intercalation/deintercalation process. At a current density of 5 A g$^{-1}$, only a small portion of the material close to the surface can be utilized for storing the charge. The $C_s$ of $\beta$-MnO$_2$, $\delta$-MnO$_2$ and $\beta$-MnO$_2@\delta$-MnO$_2$ at a current density of 5 A g$^{-1}$ retain 38.4, 34.8 and 37.2 of their initial values at a current density of 0.1 A g$^{-1}$, indicating that these three electrodes have similar rate capabilities.

Cycling stability is another critical requirement for high-performance supercapacitor. The cycling life tests for $\beta$-MnO$_2$, $\delta$-MnO$_2$ and $\beta$-MnO$_2@\delta$-MnO$_2$ were measured over 5000 continuous charge–discharge cycles between −0.15 to +0.6 V vs. Hg/HgO at a current density of 1 A g$^{-1}$ as shown in Fig. 7.

In the case of $\delta$-MnO$_2$, the $C_s$ gradually decreases with increasing cycling numbers. After 5000 cycles, ca. 75% of its initial capacitance is retained. Compared to $\delta$-MnO$_2$, $\beta$-MnO$_2$ and $\beta$-MnO$_2@\delta$-MnO$_2$ show excellent cycling stability. After 5000 cycles, the specific capacitance retention of $\beta$-MnO$_2@\delta$-MnO$_2$ is almost unchanged, and the coulombic efficiency of $\beta$-MnO$_2$ is almost 100% (98.9%) as shown in Fig. 8, suggesting that the 1D $\beta$-MnO$_2$ possesses superior cycling stability and the hierarchical core–shell structured $\beta$-MnO$_2@\delta$-MnO$_2$ using 1D $\beta$-MnO$_2$ as backbones, retain the cycling stability of the 1D $\beta$-MnO$_2$. The stability of $\beta$-MnO$_2@\delta$-MnO$_2$ is also much greater than that of other reported MnO$_2$-based electrode materials, such as NiCo$_2$O$_4$-doped carbon nanofiber@MnO$_2$ core–sheath nanostructures,\textsuperscript{28} mesoporous MnO$_2$/carbon aerogel composite,\textsuperscript{29} $\delta$-MnO$_2$ nanospheres\textsuperscript{30} and MnO$_2$ core–shell nanowires.\textsuperscript{31} In terms of charge storage mechanism in MnO$_2$-based electrodes,\textsuperscript{32} the charge storage process is based upon the adsorption/desorption of electrolyte ions, accompanied by redox conversion between Mn$^{4+}$ and Mn$^{3+}$. Based on this mechanism, the excellent cyclability of $\beta$-MnO$_2@\delta$-MnO$_2$ could be attributed to the fact that the Faradic redox process occurred near the electrode surface, which in turns may not possibly cause serious modification in the crystal structure and morphology of the electrode material. The cycling stability testing causes negligible damage on the structure of $\beta$-MnO$_2@\delta$-MnO$_2$, resulting in the excellent cycling stability. Although the surfaces of both $\beta$-MnO$_2@\delta$-MnO$_2$ and $\delta$-MnO$_2$

![Fig. 6](image1.png) Specific capacitance of $\beta$-MnO$_2$, $\delta$-MnO$_2$ and $\beta$-MnO$_2@\delta$-MnO$_2$ at different current densities in 1 M LiOH electrolyte.

![Fig. 8](image2.png) Coulombic efficiency of $\beta$-MnO$_2$, $\delta$-MnO$_2$ and $\beta$-MnO$_2@\delta$-MnO$_2$ electrodes for 5000 cycles at a current density of 1 A g$^{-1}$.
were covered by layered structure $\delta$-MnO$_2$, $\beta$-MnO$_2@\delta$-MnO$_2$ exhibits much better stability than $\delta$-MnO$_2$ since 1D $\beta$-MnO$_2$ can serve as a stable structural supportive backbone, which could reduce the structural damage during the reversible Faradaic redox reactions occurring in MnO$_2$. Meanwhile, synergistic effects between core–shell structured manganese oxides with different structures and dimensions could be another reason resulting in the improved cycling stability. The excellent cyclability of $\beta$-MnO$_2@\delta$-MnO$_2$ of the core–shell structure offers a promising target structure for future research.

The Nyquist plots of the electrochemical impedance spectroscopy (EIS) of $\beta$-MnO$_2$, $\delta$-MnO$_2$ and $\beta$-MnO$_2@\delta$-MnO$_2$ electrodes are present in Fig. 9(A). All plots show semicircles at the higher frequency region and straight lines at the lower frequency region. The diameters of the semicircles in the high-frequency region represent the Faradic charge transfer resistance of the redox reactions at the electrode–electrolyte interface. It can be observed from Fig. 9(A) that the charge transfer resistance of $\beta$-MnO$_2@\delta$-MnO$_2$ is lower than that of $\beta$-MnO$_2$ and $\delta$-MnO$_2$, suggesting that the charge transfer is the fastest one among these three samples. The straight lines on the EIS spectra correspond to the ion diffusion process in the bulk of the active mass in the low-frequency region. The slope of the straight line of $\beta$-MnO$_2$ is larger than that of $\beta$-MnO$_2@\delta$-MnO$_2$ and $\delta$-MnO$_2$, indicating that the ion diffusion resistance on $\beta$-MnO$_2$ is the smallest among the three samples. The slope of $\beta$-MnO$_2@\delta$-MnO$_2$ is slightly higher than that of $\delta$-MnO$_2$, suggesting that $\beta$-MnO$_2$ can provide faster ion diffusion in the bulk of the active mass and faster Faradic charge transfer on the interface of electrode–electrolyte when core–shell structured $\beta$-MnO$_2@\delta$-MnO$_2$ is formed. Fig. 9(B) shows the EIS curves of $\beta$-MnO$_2@\delta$-MnO$_2$ before and after 5000 cycles. It can be observed that semicircles at the higher frequency region are quite similar, indicating, after 5000 cycles, the charge transfer resistance of $\beta$-MnO$_2@\delta$-MnO$_2$ almost didn’t change. The slope of $\beta$-MnO$_2@\delta$-MnO$_2$ is slightly smaller than that of $\beta$-MnO$_2@\delta$-MnO$_2$ after 5000 cycles, suggesting that the ion diffusion resistance on $\beta$-MnO$_2@\delta$-MnO$_2$ after 5000 cycles only increase a little bit. The EIS results clearly show that the structure of $\beta$-MnO$_2@\delta$-MnO$_2$ is very stable in 1 M LiOH electrolyte. The SEM image of $\beta$-MnO$_2@\delta$-MnO$_2$ after 5000 cycles (shown in Fig. 2(D)) also confirms its structural stability.

4. Conclusions

In summary, a hierarchical $\beta$-MnO$_2@\delta$-MnO$_2$ core–shell structure with $\beta$-MnO$_2$ nano-wires as cores and layered structure $\delta$-MnO$_2$ as shells were synthesized via a simple wet chemical method. Compared to $\delta$-MnO$_2$ and $\beta$-MnO$_2$, $\beta$-MnO$_2@\delta$-MnO$_2$ shows excellent cycling stability. The capacitance retention of $\beta$-MnO$_2@\delta$-MnO$_2$ is almost unchanged with coulombic efficiency values close to 100% after 5000 cycles. It was found that the excellent cycling stability of $\beta$-MnO$_2@\delta$-MnO$_2$ arises from synergistic effects between the core–shell structured manganese oxides with different structures/dimensions and the 1D $\beta$-MnO$_2$ used as a stable structural supportive backbone, which could reduce the structural damage during the reversible Faradaic redox reactions occurring in MnO$_2$. Therefore the as-prepared $\beta$-MnO$_2@\delta$-MnO$_2$ offers a new promising cathode candidate material for alkali supercapacitors.
