Synthesis of an azo-Mn(II) complex with mild pH control using a microfluidic device

Daiki Tanaka,¹ ^{*a} Shunsuke Sawai,^a Dong Hyun Yoon,¹ Tetsushi Sekiguchi,^a Takashiro Akitsu^b and Shuichi Shoji^a

This study describes the synthesis of an azo-Mn(II) complex requiring an accurate pH control. The reaction conditions for the delicate azo-Mn(II) complex could be precisely controlled using a microfluidic device. The microfluidic method showed the following advantages over the conventional method: the concentration of the pH-control reagent was reduced (1/15), the reaction time was remarkably decreased from 4 h to less than 1 s, and the reaction temperature was lowered from 40 to 23 °C. Moreover, the microfluidic device suppressed the oxidation of the compound and did not require cooling to remove the heat of reaction. In addition, the conventional method uses harsh pH control, whereas the microfluidic device permits mild pH control.

1. Introduction

Azo-metal complexes have attracted attention from many researchers in recent years. Azo compounds have important uses in biofuel cell electrodes and solar power applications and as cell markers. For example, Lim *et al.* designed a heptamethine-azo conjugate as a near-infrared fluorescent probe to monitor mitochondrial glutathione with low background auto-fluorescence and serve as a cell marker.¹ However, the synthesis of azo-metal complexes remains challenging and is still an active area of research. For instance, Grirrane *et al.* and Zhang and Jiao have reported that gold nanoparticles supported on titanium dioxide (TiO_2) and nanoparticulate cerium dioxide (CeO_2) catalyse the aerobic oxidation of aromatic anilines to aromatic azo compounds.^{2,3} Takeda, Minakata, and co-workers demonstrated the oxidative homodimerization of aniline under various conditions.^{4–6} Monir *et al.* reported the development of an efficient method for the synthesis of aromatic azo compounds in high yields through the phenyliodine(III) diacetate (PIDA)-mediated oxidative dehydrogenative coupling of anilines.⁷ Einaga, Akitsu, and co-workers systematically investigated organic/inorganic hybrid materials composed of metal complexes and azo compounds in poly(methyl methacrylate) films as non-crystalline solids⁸ that could be converted into chiral Schiff base complexes and made to regularly align.⁹ However, the synthesis of azo compounds *via* conventional methods is complicated because it requires a metal catalyst and strict control of the atmosphere and temperature.

Herein, we propose a new synthetic method for a very simple azo-metal complex using a microfluidic device. Chemical processes using microfluidic devices can be highly efficient. For example, Priest *et al.* reported the microfluidic solvent extraction of Cu^{2+} ions from particle-laden aqueous solutions using 2-hydroxy-5-nonylacetophenone as an alternative to conventional solvent extraction.¹⁰ Furthermore, Kitamori and co-workers described the determination of carbamate pesticides such as carbaryl, carbofuran, propoxur, and bendiocarb using a microfluidic device developed for efficient solvent extraction.^{11,12} Brivio *et al.* and deMello *et al.* reviewed the effects of downscaling reaction vessels as well as the advantages of the continuous-flow microfluidic approach over conventional methods, as illustrated by a number of examples of organic reactions carried out in microfluidic devices.^{13–16} The Lumley group reported the use of a microfluidic device in the photochemical oxidation of cholesterol, α -terpinene, and citronellol under flow conditions, and the results were compared with those of similar batch reactions.¹⁷ Miller *et al.* described the rapid and high-yielding carbonylative cross-coupling reactions of aryl halides to form secondary amides using a glass-fabricated microfluidic device.¹⁸ Gunther and Jensen reviewed the flow characteristics in multiphase micro- and nanoscale systems, measurement methodology, and how these characteristics could be utilized in microfluidic applications.¹⁹

Kanai *et al.* described a sheath flow multi-sample injector that allowed concentration-conserving sample injection using a step-wise flow to reduce the dilution of the sample reagent.²⁰ We have previously established the synthesis of metal complexes and protein–metal complexes using microfluidic devices.^{21,22} The synthesis of the metal complexes using the microfluidic device required a shorter reaction time and no temperature or atmospheric control.^{23,24} Furthermore, the conventional synthesis of

Fig. 1 pH control in the conventional method.

azo compounds requires harsh pH adjustments using high concentrations of hydrochloric acid and sodium hydroxide. However, highly concentrated reagents lead to decomposition of the compounds (Fig. 1). In addition, these conventional methods require cooling to remove the heat of reaction.

In this study, we demonstrate the use of a microfluidic device to synthesise azo compounds under milder conditions than those utilized in conventional methods. According to previous studies, microfluidic devices can permit a more than 10 000-fold increase in the rates of chemical reactions.^{23,24} We, therefore, focused on the high reactivity that could be achieved with a microfluidic device. The device is likely to reduce the required concentration of pH-adjustment reagents. Moreover, the microfluidic device allows reactions to be performed at the interface between reagents. The reagents are supplied one after another, and the reactants for each step are synthesised in a stepwise manner. Thus, localised excess chemical reactions do not occur. Furthermore, the conventional method requires complicated operations, thus making the synthesis difficult. However, the use of a microfluidic device eliminates the need to control these operations and allows the convenient and user-friendly synthesis of azo-Mn(II) complexes.

2. Experimental

2.1 Materials and measuring equipment

The chemicals and reagents were of the highest grade commercially available (Tokyo Chemical Industry; Kanto Chemical) and used as received without further purification. The products were analysed by infrared spectroscopy (IR; FT/IR-6200, JASCO), ultraviolet-visible spectroscopy (UV-vis; U-3900, Hitachi), fast atom bombardment mass spectrometry (FAB-MS; JMS-BU25, JEOL), time-of-flight mass spectrometry (TOF-MS; JMS-T100LC, JEOL), proton NMR spectroscopy (¹H-NMR; ECX500, JEOL), and X-ray diffraction (XRD; RINTULTima3, Rigaku). The conventional synthesis and the synthesis conducted using the microfluidic device were compared.

2.2 Conventional synthesis

As shown in Fig. 2, the azo-Mn(II) complex was synthesised in three steps following the method reported by Akitsu *et al.*²⁵ Steps I, II, and III represent the syntheses of an azo compound, azo ligand, and azo-Mn(II) complex, respectively. Steps II and III were performed under a nitrogen atmosphere.

Fig. 2 Three-step synthesis of the azo-Mn(II) complex.

2.2.1 Synthesis of azo compound (step I). The synthesis was performed under cooling with ice. Aniline (250 mmol L⁻¹, reagent A) and sodium nitrite (250 mmol L⁻¹, reagent B) were added dropwise to an aqueous HCl solution (5.62 mol L⁻¹) under stirring for 30 min to form the diazonium compound. Then, *o*-vanillin (250 mmol L⁻¹, reagent C) was added to the solution of the diazonium compound, which was neutralised using NaOH, and the resulting mixture was stirred for 30 min to afford an orange compound that was identified as the azo compound *via* the IR, FAB-MS, and ¹H-NMR analysis.

2.2.2 Synthesis of azo ligand (step II). The azo compound (40 mmol L⁻¹) was added dropwise to a solution of (1*R*,2*R*)-(+)-1,2-diphenylethylenediamine (20 mmol L⁻¹, reagent D) dissolved in methanol (50 mL), and the resulting mixture was stirred at 40 °C for 2 h to afford an orange solution of the ligand.

2.2.3 Synthesis of azo-Mn(II) complex (step III). Mn(II) acetate tetrahydrate (20 mmol L⁻¹, reagent E) was added to the abovementioned solution to obtain a red solution of the complex. After being stirred for 2 h under N₂ gas, the complex was filtered off as a red prismatic precipitate (Fig. 3), and the product was analysed *via* UV-vis spectroscopy, TOF-MS, ¹H-NMR, and XRD.

2.3 Synthesis with the microfluidic device

2.3.1 Design and fabrication of the microfluidic device. The designs of the simple Y-junction and X-junction devices used in this study are shown in Fig. 4. The width of the channel

Fig. 3 Synthetic scheme for the azo-Mn(II) complex.

Fig. 4 Device design and fluidic experiments. (a) Y-junction device. (b) X-junction device.

Table 1 Preliminary experimental conditions for pH control

HCl concentration	Synthesis result
1/1 (5.62 mol L ⁻¹)	Failure
1/2 (2.81 mol L ⁻¹)	Failure
1/5 (1.12 mol L ⁻¹)	Failure
1/10 (0.56 mol L ⁻¹)	Success
1/15 (0.37 mol L⁻¹)	Success
1/20 (0.28 mol L ⁻¹)	Insoluble (aniline)

was approximately 500 μm, and the depth was approximately 100 μm. The device was fabricated *via* the standard soft lithographic technology. Reagents and solutions were introduced by a syringe using a syringe pump.²⁴

2.3.2 Preliminary experiments – synthesis of the azo compound (step I). We conducted preliminary experiments to determine the appropriate concentration of the pH-adjustment reagent for the fluidic experiments (Table 1). The preliminary concentrations of HCl and NaOH selected were 1/1 (5.62 mol L⁻¹), 1/2 (2.81 mol L⁻¹), 1/5 (1.12 mol L⁻¹), 1/10 (0.56 mol L⁻¹), and 1/15 (0.37 mol L⁻¹) as compared to those used in the conventional method. The synthetic experiments failed at the concentrations 1/1, 1/2, and 1/5, and only black decomposition products were obtained. The synthetic experiments at the concentrations 1/10 and 1/15 afforded orange compounds. Moreover, at the HCl

concentrations below 1/15, aniline did not dissolve in the aqueous solution. We, therefore, decided to conduct the subsequent synthetic experiments at a concentration of 1/15 because this mild pH control does not lead to the decomposition of the azo compound.

2.3.3 Synthesis of the azo compound (step I). A simple Y-junction channel was used for step I (Fig. 4a). The azo compound was synthesised using aniline (250 mmol L⁻¹, reagent A), sodium nitrite (250 mmol L⁻¹, reagent B), and *o*-vanillin (250 mmol L⁻¹, reagent C). Aniline was dissolved in an aqueous HCl solution (0.37 mol L⁻¹), and *o*-vanillin was dissolved in an aqueous NaOH solution (0.37 mol L⁻¹). This synthetic step was performed in the two channels of the Y-junction microfluidic device at a flow rate of 2 μL min⁻¹. The synthesised azo compound was filtered and analysed *via* IR, FAB-MS, and ¹H-NMR (Table 2).

2.3.4 Synthesis of the azo ligand (step II). In step II of the synthesis, a Y-shaped microfluidic device was used (Fig. 4a). The ligand was synthesised from the azo compound (40 mmol L⁻¹, step I product) and (1*R*,2*R*)-(+)1,2-diphenylethylenediamine (20 mmol L⁻¹, reagent D) at a flow rate of 2 μL min⁻¹ (Table 2).

2.3.5 Synthesis of the azo-Mn(II) complex (step III). The azo-Mn(II) complex was synthesised from the azo ligand and Mn(II) acetate tetrahydrate (20 mmol L⁻¹, reagent E), both of which were dissolved in methanol. Step III of the synthesis was performed in the second channel of the X-junction microfluidic device (Fig. 4b). This synthesis was performed directly after step II with no treatment, with the outlet from step II connected to the ligand inlet for step III. The flow rate was 4 μL min⁻¹. After the synthesis, the solvent was evaporated to afford the product, which was analysed by UV-vis spectroscopy, TOF-MS, ¹H-NMR, and XRD (Table 2). However, XRD measurement data could not be obtained.

3. Results and discussion

The FAB-MS results show the mass-to-charge ratio (*m/z*: [256.08 + H]⁺) of the products obtained after step I for both the conventional method and the microfluidic device method (Fig. 5). In addition, the ¹H-NMR spectra of the products obtained from the two methods were consistent (Fig. 6).

Table 2 Summary of the synthetic conditions

	Conventional method	Microfluidic device
Reagent concentration (step I), HCl and NaOH for pH control	5.62 mol L ⁻¹	0.37 mol L ⁻¹
Reagent concentration (step I), azo compounds	250 mmol L ⁻¹	250 mmol L ⁻¹
Reagent concentration (steps II and III), azo-metal complex	20 and 40 mmol L ⁻¹	20 and 40 mmol L ⁻¹
Reaction temperature (step I)	0–5 °C	23 °C (R.T.)
Reaction temperature (steps II and III)	40 °C	23 °C (R.T.)
Flow rate	—	2 and 4 μL min ⁻¹
Stirring time (step I)	1 h	—
Stirring time (steps II and III)	4 h	—
Atmosphere	N ₂	Air
Synthesis scale	50 cm ³	0.002 cm ³
Analytical method for the azo compound (step I)	IR, FAB-MS and ¹ H-NMR	
Analytical method for the metal complex (step III)	UV-vis, TOF-MS, ¹ H-NMR and XRD	

Fig. 5 FAB-MS spectra of the azo compounds obtained in step I of the conventional method and using the microfluidic device.

Furthermore, a peak corresponding to $\text{N}=\text{N}$ (1590 cm^{-1}) was observed in the IR spectra (Fig. 7a). These analytical data showed that both the conventional and microfluidic device methods successfully afforded the azo compound. This result proved that the azo compound could be synthesised under mild pH control using the microfluidic device. The chemical reaction was promoted using the microfluidic device, and the reaction proceeded even at a low HCl concentration. Moreover, the synthesis in the microfluidic device did not require temperature control (Table 3) as the microfluidic device allowed the reaction to occur at the interface. The reagents were supplied one after another, and the reactants for each step were synthesised in a stepwise manner. The synthesis of difficult azo compounds requiring control of pH and temperature is also possible using microfluidic devices.

We also tested a microfluidic device with a channel width of $200\text{ }\mu\text{m}$. However, this device could not be used for the synthesis because the azo compound immediately clogged the channels. Therefore, in the experiments reported herein, we synthesised the azo compound using a microfluidic device with a channel width of 1 mm .

The UV-vis spectra (Fig. 7b) revealed changes in the detected $\pi-\pi^*$ and charge-transfer transitions, which indicated that the azo-Mn(ii) complex had been obtained. In addition, the TOF-MS data showed peaks for the azo-Mn(ii) complex ($m/z: 741.2$; Fig. 8). Moreover, the large peaks in the $^1\text{H-NMR}$ spectra were consistent (Fig. 9). Overall, these results indicated that the azo-Mn(ii) complex had been successfully synthesised using the microfluidic device.

XRD measurement data could not be obtained. In the conventional method, a large amount of solvent can be gradually evaporated to promote crystal growth. Conversely, a small amount of solvent obtained using the microfluidic device method rapidly evaporated. For this reason, the product herein was obtained as a powder rather than as a crystal, and the XRD spectra could be adequately obtained.

Microfluidic devices have been suggested to lead to high reaction rates. For steps II and III, the microfluidic device was operated at room temperature and the conventional method was conducted at $40\text{ }^\circ\text{C}$. In addition, the conventional method required a reaction time of 4 h , whereas the reaction in the microfluidic device completed in less than 1 s .

Table 3 Comparison between the microfluidic device and the conventional method

Parameter	Conventional method	Microfluidic device
pH control (step I), HCl and NaOH	5.62 mol L ⁻¹	0.37 mol L ⁻¹
Reaction temperature (step I)	0–5 °C	23 °C (R.T.)
Reaction temperature (steps II and III)	40 °C	23 °C (R.T.)
Synthesis time (step I)	1 h	1 s
Synthesis time (steps II and III)	4 h	1 s
Atmosphere	N ₂	Air

Furthermore, the synthesis using the conventional method needed to be performed under a N₂ atmosphere, whereas it could be performed under an air atmosphere using the microfluidic device. Zhang and Cloud reported that oxygen could easily pass through a polydimethylsiloxane (PDMS) device.²⁶ However, Tanaka *et al.* have also described the synthesis of

Mn(II) and Co(II) salen complexes using microfluidic devices.²⁴ In this study, the reaction time was too short for the reagents to react with oxygen because they flowed continuously into the microfluidic device. However, in the conventional method, the reaction mixture was stirred, and metal acetate was oxidised. Furthermore, PDMS is not affected by alcohol.²⁷ The quantities that microfluidic devices can handle are small although this problem can be solved using multiple devices in parallel. In microfluidic devices, reactions occur rapidly and are isolated from the air. Therefore, syntheses, which cannot be achieved *via* conventional methods, such as simultaneous organic and complex reactions, can be achieved using microfluidic devices.

One drawback of the chemical synthesis using the microfluidic device was the formation of a byproduct (*m/z*: [331.83 + H]⁺) derived from the azo compound, as shown in Fig. 5. In addition, the π-π* band in Fig. 7b indicated that the ligands were mixed with the azo-Mn(II) complex. Furthermore, Fig. 9 indicated that unreacted materials were mixed with the desired products. However, this problem could be solved using a microdroplet merging device, and we will investigate the use of this device in our future work to prevent the inclusion of unreacted materials.

Fig. 8 TOF-MS spectra of the azo-Mn(II) complex obtained in step III of the conventional method and using the microfluidic device.

Fig. 9 ^1H -NMR spectra of the azo-Mn(II) complex obtained in step III of the conventional method and using the microfluidic device.

4. Conclusion

An azo-Mn(II) complex was synthesised with mild pH control using a highly reactive microfluidic device. We successfully synthesised azo compounds requiring temperature control and pH control using a simple Y-junction microfluidic device. In addition, the microfluidic device formed the azo-Mn(II) complex in less than 1 s at room temperature, and the synthesis could be performed under an air atmosphere. The microfluidic device is capable of chemical synthesis similar to the conventional method although it is better suited to handling valuable and dangerous reagents. In future work, we will synthesise azo-metal complexes containing lysozyme as azo-metal complexes have optical isomerisation properties that may allow us to achieve the goal of controlling fuel cells using light. It should be noted that the amount of product generated using the microfluidic device is small. We intend to solve this problem by fabricating an integrated device that should enable practical chemical synthesis.
