Integration of transcriptome and proteome data reveals ochratoxin A biosynthesis regulated by pH in *Penicillium citrinum*

Lina Zhao,^a Yaping Peng,^a Xiaoyun Zhang,^a Jun Li,^b Xiangfeng Zheng,^a Qiya Yang,^a Maurice Tibiru Apaliya^a and Hongyin Zhang^{ib}*^a

Ochratoxin A (OTA) has been found in a wide range of commodities and is highly toxic to both humans and animals. Therefore, a good understanding of the mechanisms of OTA production by fungi will contribute to the development of eco-friendly methods to mitigate this toxin. In this study, the results showed that *Penicillium citrinum* X9-4, which was isolated from infected grapes in our laboratory, produced the highest amount of OTA at pH 5 in culture media, and toxin production was restrained under an acidic environment (pH 3). Then, differentially expressed proteins of *P. citrinum* X9-4 cultured under these two conditions were analyzed by proteomic technology. Additionally, through the analysis of the transcriptome data of *P. citrinum* cultured at pH 3 and 5, the differentially expressed genes have been found to be involved in many metabolic pathways including amino acid transport and metabolism, transport and metabolism of carbohydrates, inorganic ion transport and metabolism, biosynthesis of secondary metabolites, and energy and supply metabolism, which are likely to be involved in the regulation of OTA biosynthesis. It was also revealed that the expression levels of some OTA synthesis-related enzymes, such as acetyltransferase, acyl coenzyme A oxidase, alcohol oxidase, cytochrome P450, acetyl xylan esterase, and turn ketol enzyme, and genes for the regulation of toxin synthesis pathways were reduced under acidic culture conditions.

1 Introduction

Ochratoxin A (OTA) is found in a variety of plant and animal products after infection of the produce by filamentous species belonging to some genera of *Aspergillus* and *Penicillium*. OTA is classified as a possible human carcinogen (Group 2B) by the International Agency of Research on Cancer (IARC, 1993), and it exhibits nephrotoxicity, hepatotoxicity, neurotoxicity, teratogenicity, and immunotoxicity;^{1–3} hence, it poses potential hazard to human and animals. OTA is a common mycotoxin contaminant of a wide range of foods and their products, which includes cereals, grapes, coffee, nuts, spices, cocoa beans, and other products processed from these substances. After cereals, grapes and its derived products are the second most contaminated products with OTA. The role of OTA in the etiology of Balkan endemic nephropathy and its association with urinary tract tumors have also been proved. OTA forms a benzoquinone electrophile following activation by cytochrome P450 enzymes and radical species triggered by enzymes with peroxidase activities.^{4,5} OTA is particularly toxic to the human body due to

its high stability.⁶ Based on the strong toxicity and pathogenicity of OTA, some organizations and institutions have established official regulations and guidelines for maximum levels of OTA content in food.

OTA was first reported to be caused by *Penicillium verrucosum* and *Aspergillus ochraceus* in cereals and its derived products.⁷ The main OTA-producing strains include *Penicillium*⁸ and *Aspergillus* genera, a few *Petromyces* genera, and *Cladosporium* strains.^{9–11} Black aspergilli (*i.e.*, *Aspergillus niger* and *Aspergillus carbonarius*) have been found to produce OTA in commodities such as wine, grapes, and raisins in occident.¹² The rate of OTA synthesis is influenced by the kind of substrate contamination, environmental conditions, and geographical regions.¹³ In temperate climate, OTA is mainly produced by *Penicillium* species, whereas in tropical and subtropical areas, it is produced by *Aspergillus* species.¹⁴

Although the pathway of OTA biosynthesis has not been completely elucidated in detail to date, some steps of the toxin biosynthesis pathway have been clearly elucidated.^{15–17} It is clear that the pathway of ochratoxin biosynthesis involves several crucial steps such as biosynthesis of the isocoumarin group through a reaction catalyzed by polyketide synthase (PKS), ligation of the isocoumarin group with amino acid phenylalanine through the carboxyl group in a reaction catalyzed by a peptide synthetase, and chlorination; however, the order of

^aSchool of Food and Biological Engineering, Jiangsu University, Zhenjiang 212013, Jiangsu, People's Republic of China. E-mail: zhanghongyin126@126.com

^bSchool of the Environment and Safety Engineering, Jiangsu University, Zhenjiang 212013, Jiangsu, People's Republic of China

the reactions is not well defined to date.¹⁸ There is a clear evidence of the involvement of polyketide synthase in OTA production in *A. ochraceus*,¹⁹ *Penicillium nordicum/verrucosum*,²⁰ and *A. carbonarius*,²¹ and the involvement of the non-ribosomal peptide synthetase (*nrps*) has been unequivocally demonstrated in *A. carbonarius* only.²² The pathway is still fragmentary, and some genes are missing during the virtual overlap between the hypothesized biochemical pathway and the genes found in putative OTA clusters of both *Aspergillus* and *Penicillium*.^{19,23} It is reported that mycotoxin biosynthetic genes are often coordinately regulated and arranged in clusters.^{24–26}

Studies based on differential expression profiles are often performed to identify genes and proteins related to OTA biosynthesis. To identify the putative OTA biosynthetic genes in *A. ochraceus*, O'Callaghan *et al.*¹⁵ focused on two putative cytochrome P450 monooxygenase genes by comparing their expression profiles in permissive and restrictive media. Additionally, it was reported that polyketide synthase gene (*pks*) and nonribosomal peptide synthetase gene (*nrps*) were related to OTA biosynthesis in *P. nordicum*.²⁷ A putative OTA biosynthetic cluster has been identified, containing biosynthetic genes encoding (i) PKS (*otapksPN*), (ii) nonribosomal peptide synthetase (NRPS) (*otanpsPN*) putatively responsible for the formation of the peptide bond between polyketide and phenylalanine, (iii) a gene (*otachIPN*) with some homology to chlorinating enzymes, which may be involved in the chlorination step, and (iv) a gene (*otatraPN*) with high homology to a transport protein hypothesized to be involved in OTA export.²⁸ An interesting thing is that *otapksPN* gene is present only in *P. nordicum* and not in *P. verrucosum*; this indicates that genetic differences also exist between both OTA-producing *Penicillium* species.²⁹ However, none of the necessary genes for the biosynthesis of this harmful toxin have been found to date.

The effect of pH on the growth and OTA production of *P. citrinum* was investigated. Proteomics and transcriptomic analysis of *P. citrinum* cultured at different pH values were performed to reveal the underlying mechanisms of OTA biosynthesis regulated by pH. This study will reveal the regulation mechanisms of OTA biosynthesis, enrich the gene database of OTA production genera, and assist in developing effective strategies for the protection of food and feed from OTA contamination.

2 Materials and methods

2.1 Fungal strains

P. citrinum X9-4 was isolated from the infected grape berries in our laboratory and deposited in the China Center for Type Culture Collection (CCTCC), and the collection number was CCTCC AF 2016008. The strain *P. citrinum* X9-4 was incubated on a potato dextrose agar medium (PDA: 200 mL of extract from 200 g boiled potatoes, 20 g dextrose, 20 g agar, and 800 mL distilled water) for 7 days at 25 °C before being used for the experiment; then, conidia were counted using a hemocytometer and adjusted to a concentration of 1×10^6 conidia per mL with sterile distilled water. OTA production was determined using Czapek Yeast Extract agar (CYA, purchased from Oxoid Ltd.,

Basingstoke, Hampshire, England), which contained (per liter of medium) 1 g KH_2PO_4 , 10 mL *Cza*-concentrate, 1 mL trace metal solution, 5 g yeast extract, 30 g sucrose, and 15 g agar.

2.2 pH assay and determination of the growth and OTA production of *P. citrinum*

The pH value of the medium was adjusted to 3, 5, 7, 9, and 11 by adding HCl or NaOH before autoclaving. The pH value was measured using the pH meter PHS-3B (Shanghai Lida Instrument Factory, Shanghai, China). For the acidified medium (pH 3.0), agar was sterilized separately and then added to the sterilized medium to avoid solidification. The pH value of each medium was checked after sterilization. Aliquots of 100 μL of *P. citrinum* spore suspension with a concentration of 1×10^6 conidia per mL were inoculated using the Petri dish-smearing method. Petri dishes were incubated at 25 °C in dark. Each assay was performed in duplicate. Then, two weeks after inoculation, mycelium and spores were obtained for protein and RNA extraction.

To determine the mycelium growth of the strain *P. citrinum* X9-4 under different culture conditions, the colony diameter was chosen as the evaluation index. Then, 2.5 μL of 1×10^6 conidia per mL of *P. citrinum* X9-4 was inoculated in the single point of the culture solid medium at 25 °C ($a_w = 90\%$) for 7 days; after this, the colony diameter was measured using a Vernier caliper. Each plate was measured three times, and the experiment was repeated twice. For the determination of OTA production of the strain X9-4 under different pH culture conditions, 100 μL of 1×10^6 conidia per mL of *P. citrinum* X9-4 was spread by a coated rod on CYA plates (containing 30 mL CYA medium) for 2 weeks; then, a whole plate was extracted using 5 mL methanol by shaking to obtain a uniform mixture and deposited in dark for 3 hours. The extracts were filtered through a 0.22 μm filter for OTA detection. OTA production was determined by a high-performance liquid chromatograph equipped with a fluorescence detector (Agilent Technologies 1260, America). Agilent ZORBAX SB-C18 reversed-phase HPLC analytical column (250 mm \times 4.6 mm, 5 μm) was used, and the column temperature was 30 °C. The excitation and emission wavelengths were set at 330 nm and 460 nm, respectively. The mobile phase comprised a mixture of acetonitrile and 1% acetic acid (60 : 40, v/v) at a flow rate of 1 mL min^{-1} in the isocratic elution mode.

2.3 Proteome analysis

2.3.1 Total protein extraction. To extract proteins, the abovementioned mycelium and spores were cultured at the pH values of 3 and 5; after being harvested, they were ground into powder using liquid N_2 . The powder was homogenized in an Eppendorf tube containing 10 mL of cold TE buffer (1.518 g Tris-base, 0.073 g EDTA, adjusted to pH 8.0 with 1 M HCL, dissolved with MilliQ water to 250 mL, and stored at 4 °C). Then, 174 μL of PMSF (1 mmol mL^{-1}) was added to the homogenate and mixed by vortexing for 30 s; then, it was stored at 4 °C for 30 min to inactivate the proteases. Next, 50 $\mu\text{g mL}^{-1}$ RNase A and 200 $\mu\text{g mL}^{-1}$ DNase were added and kept at 4 °C for 30 min

to hydrolyze DNA and RNA in the homogenate. The homogenate was centrifuged for 30 min at $12\,000 \times g$, and the supernatant was transferred into a new Eppendorf tube; after this, equal volume of acetone containing 20% TCA was added. The protein was then precipitated at $-20\text{ }^\circ\text{C}$ for 12–16 hours. The precipitated proteins were obtained after centrifugation for 60 min at $12\,000 \times g$, and then, the precipitate was washed twice with cold acetone (stored at $-20\text{ }^\circ\text{C}$ more than 30 min) and centrifuged for 10 min at $12\,000 \times g$. The precipitate was centrifuged instantaneously, and all visible liquid in the tube was discarded. Then, the protein extracts were air-dried for 5 min before being dissolved in 100 μL lysis buffer (2 M thiourea, 7 M urea, 4% (w/v) CHAPS, 65 mM DTT, and 0.2% (v/v) carrier ampholytes/Bio-Rad) and stored at $-80\text{ }^\circ\text{C}$ until further analysis.

2.3.2 Two-dimensional gel electrophoresis. Protein extracts for isoelectric focusing and two-dimensional gel electrophoresis were initially quantified using a UV-1601 spectrophotometer (Shimadzu, Japan). Values were verified using modified Bradford-Assay according to Marion M. Bradford³⁰ using bovine serum albumin (BSA) as a standard. Isoelectric focusing and two-dimensional gel electrophoresis were carried out in biological triplicates for each growth condition. Isoelectric focusing was performed *via* GE Ettan IPGphor 3 using 24 cm ImmobilineTM Drystrip gels with an immobilized pH-gradient, linear from pH 3 to 10; the two-dimensional gel electrophoresis was conducted according to the instructions of the GE manufacturer. A maximum voltage of 3000 V was reached within 4 h and held for 65 000 V h. After focusing, the strips were kept at 500 V (for no more than 15 h) to prevent deviation of the focused proteins until they were used directly for electrophoresis. Proteins were separated using EttanDALTSix. Electrophoresis System was carried out in SDS electrophoresis buffer (25 mM Tris, pH 8.8, 192 mM glycine, and 0.1% SDS) at 1 W per strip for 1 h and then at 15 W per strip until the BPB solvent settled at the bottom of the gels. All abovementioned instruments were purchased from GE Healthcare. The gels were stained using a modified Coomassie-protocol, washed twice with MilliQ water, and then stained for 2 h in Coomassie staining solution (45% methanol, 45% MilliQ water, 10% glacial acetic acid, and 2.5 g R250). After being stained, the gels were washed with discoloration solution (45% alcohol, 45% MilliQ water, and preserved in 10% glacial acetic acid).

2.3.3 Image analysis. The gels were scanned using Image scanner III and statistically analyzed using Image Master 7.0 analysis software for spot detection and matching. Protein spot scan intensities were analyzed using a *t*-test with implemented normalization, and proteins were classified as significantly regulated when $p < 0.05$. All the abovementioned instruments were purchased from GE Healthcare.

MS analysis was performed as described by Zhang *et al.*,³¹ with some modifications. Selected spots were manually excised from gels and placed in Eppendorf tubes. Each gel piece of protein was washed with 350 μL of deionized water for 10 min, and the procedure was repeated twice. Afterward, the gel pieces were dehydrated with 50 μL of 10 mM $(\text{NH}_4)_2\text{CO}_3$ /acetonitrile (1 : 1) for 10 min. This process was repeated until the color faded. Then, the gel pieces were dehydrated with 25 mM

$(\text{NH}_4)_2\text{CO}_3$ and 50% acetonitrile. Next, 3 μL trypsin solution (10 ng μL^{-1} trypsin in 25 mM $(\text{NH}_4)_2\text{CO}_3$) was added, and the mixture was kept at $4\text{ }^\circ\text{C}$ for 30 min until the entire trypsin solution was absorbed by the gel pieces. The gel pieces were then covered with 15 μL of 25 mM $(\text{NH}_4)_2\text{CO}_3$ and digested at $37\text{ }^\circ\text{C}$ overnight for proteolysis. After this, 2% TFA was added and centrifuged immediately to terminate the reaction. Herein, 1 μL of the peptide solution was spotted per well in perforated plates and evaporated at room temperature, and this step was repeated once.

2.3.4 HPLC-ESI-TOF-MS/MS analysis of protein spots. Mass calibrations were carried out using a standard peptide mixture. Mass spectra were acquired using a matrix-assisted laser desorption/ionization time of flight (MALDI-TOF) mass spectrometer (Bruker Daltonics, Germany).

The identification of the vast majority of the proteins was performed using search engine MASCOT Peptide Mass Fingerprint of Matrix Science and compared with NCBI nr Swissport databases. The parameters used for MS search included taxonomy, all series; allowed modifications, carbamidomethyl of cysteine (fixed) and oxidation of methionine (variable); and peptide tolerance, ± 0.3 Da. Only the highest Mowse score was considered as the most probable identification and was significant ($p < 0.05$) when protein scores were greater than 88 (NCBI nr) or 70 (swissport). The data were analyzed by analysis of variance (ANOVA) using the statistical program SPSS/PC version II.x, (SPSS Inc. Chicago, Illinois, USA), and the Duncan's multiple range test was used for mean separation. In addition, when two groups of data were compared, the independent-sample *t* test was applied for mean separation. The statistical significance was assessed at $p < 0.05$.

2.4 RNA extraction and transcriptome sequencing

2.4.1 RNA extraction. Total RNA was isolated from aliquots of 0.1 g of mycelia using TRIzol (Tiangen Biotech, Beijing) in accordance with the manufacturer's instruction from abovementioned mycelium and spores when cultured at the pH values of 3 and 5. The integrity of RNA was analyzed using the RNA Nano 6000 Assay Kit of the Agilent Bioanalyzer 2100 system (Agilent Technologies, CA, US). The concentration and purity of RNA were measured by the NanoDrop 2000 spectrophotometer (Thermo Fisher Scientific, Wilmington, DE).

2.4.2 Construction of cDNA library and illumina sequencing. Each RNA sample of *P. citrinum* cultured at pH 3 and 5 was used to perform RNA-seq. Herein, three micrograms of high-quality RNA of each sample was used for cDNA library construction and sequencing. Enrichment of mRNA was conducted using magnetic Oligo (dT) beads. RNA sequencing libraries were generated using the NEBNext[®] Ultra RNA Library Prep kit for Illumina (New England Biolabs, Ipswich, MA, U.S.A.) with multiplexing primers, according to the manufacturer's instructions. The cDNA library was constructed with average inserts of 200 bp (150–250 bp), with non-stranded library preparation. cDNA was purified using AMPure XP Beads (Beckman Coulter, Inc.). Purified double cDNA chains were subjected to end repair and adapter ligation; then, the

suitable fragments were selected by Agencourt AMPure XP beads (Beckman Coulter, Inc.), and cDNA library was obtained by PCR enrichment. The Agilent 2100 bioanalyzer and ABI StepOnePlus Real-Time PCR System were used to quantify and qualify the cDNA sample library, respectively. Finally, the library was sequenced *via* the Illumina HiSeq2500 with the pair-end mode (performed by Genepioneer Biotechnologies Company).

2.4.3 Bioinformatics analysis of the RNA-Seq data. High-quality clean reads were obtained by removing the adaptor sequences, duplicated sequences, ambiguous reads (N), and low-quality reads. Transcriptomes data were separately assembled *de novo* using Trinity (<http://trinityrnaseq.sourceforge.net/>). To obtain the annotation information of unigenes, the unigene sequences of *P. citrinum* were searched using BLAST and compared with those obtained using the NR, Swissprot, GO, COG, KOG, and KEGG databases. The FPKM method was used to estimate the gene expression levels. The DEGSeq R package (1.20.0) was used to analyze the differential expression in two samples. The GO (Gene Ontology) database and COG (Cluster of Orthologous Groups of proteins) database were used to classify differentially expressed genes. The transcriptome data have been submitted to the Gene Expression Omnibus (GEO) database, and the GEO accession number is GSE102600.

2.5 Reverse transcription and real-time quantitative PCR

Herein, one microgram of DNase-treated RNA was reverse-transcribed using a reverse transcription kit (Thermo Scientific, Lithuania). The RT-qPCR reactions of interested genes were performed using the SYBR Premix Ex Taq™ (Tli RNaseH Plus) quantitative fluorescence kit (TaKaRa, Dalian, China) in ABI StepOnePlus Real-Time PCR Systems (Applied Biosystems, CA, USA) following the manufacture's instructions. The primers used for amplification were designed using primer 5, with the product size between 150 and 250 bp, and the primer sequences are listed in Table 3. The relative expression was calculated using the $2^{-\Delta\Delta C_t}$ method, as described by Schmittgen and Livak.³² Actin binding gene was used as an internal reference. In this pH assay, the reference was a pH 3.0 medium.³³

3 Results and discussion

3.1 Effect of pH on the growth and OTA production of the strain X9-4

The growth of *P. citrinum* X9-4 is shown in Fig. 1. The strain could grow within a wide pH range, but the alkaline environment was unsuitable for its growth. When the strain was cultured at pH 11, the colony diameter was 12 mm, half of that of the strain cultured at pH 7, which was the most favorable pH for growth. In contrast, colony diameters were very close when the pH of the culture medium was between 3 and 9. With regard to the influence of pH on toxin production by the strain, toxin production was high in the medium with pH 5 and 9, and the highest concentration of the toxin was 25.6 ng g⁻¹ at pH 5. It was also observed that when the strain was cultured at pH 3, no OTA was detected; this indicated that its biosynthesis was inhibited in an acidic environment.

Fig. 1 Colony diameter and OTA production of *P. citrinum* at different pH values. Values are means of two independent experiments. Error bars represent the standard error of the mean. Data in columns with the different letters are significantly different according to the Duncan's multiple-range test at $P < 0.05$.

It was found that the OTA-producing strain *A. niger* not only adapted to a wider pH range for growth, but also produced OTA in a wider pH range.³⁴ It was also reported that *A. carbonarius* and *A. niger* could grow and produce OTA well in a wider pH range,³⁵ and the highest level of OTA production was observed at pH 5.35. Our result was well consistent with that reported by Passamani about the effect of pH on OTA production in *A. carbonarius* and *A. niger*.³⁵

3.2 Relative expression of proteins involved in OTA biosynthesis in response to different pH conditions

The production of OTA by *P. citrinum* in an acidic environment was lower than the minimum limit of detection of an HPLC fluorescence detector, but OTA concentration reached 25.6 ng g⁻¹ at pH 5. This means that OTA production under acidic conditions is restrained. To investigate the mechanism of how an acidic environment restricts the OTA biosynthesis, total proteins of *P. citrinum* cultured at pH 3 and 5 were extracted. As shown in Fig. 2, a total of 300 protein spots were detected on each gel using PDQuest, containing 90 differentially expressed proteins (ratio ≥ 2.0), and 25 of the best-resolved spots were identified by MALDI-TOF/TOF MS (Table 1).

Fig. 2 Two-dimensional pattern of total proteins of *P. citrinum* cultured at different pH values. (A) *P. citrinum* cultured at pH 3, (B) *P. citrinum* cultured at pH 5.

3.3 Analysis of the differentially expressed proteins

The synthesis of OTA by *P. citrinum* may be associated with basic metabolism (Fig. 3). When *P. citrinum* was cultured at pH 5, metabolism- and synthesis-related proteins, such as fructose-bisphosphate aldolase (FBA, spots 11 and 4) and nucleoside-diphosphate-sugar epimerase were up-regulated. FBA can reversibly catalyze fructose 1,6-diphosphate to two triose, dihydroxyacetone phosphate and glyceraldehyde 3-phosphate. This reaction exists in both glycolytic/gluconeogenesis pathway and pentose phosphate pathway (PP pathway), which provide energy and substrate for biological synthesis and metabolism. Transaldolase (spot 14) was down-regulated when *P. citrinum* was cultured at pH 5. This enzyme is involved in PP pathway and can transfer the dihydroxyacetone part of 7-phosphosedoheptose to glyceraldehyde-3-phosphate, thus the down-regulation of transaldolase may be decreased acetone necessary for OTA synthesis in *P. citrinum*.

Energy is essential for the biosynthesis of OTA, and PP pathway is an important source to provide NADPH.³⁶ In this study, the expression of 6-phosphogluconate dehydrogenase (6PGDH, spot 25) was decreased when the strain was cultured at

pH 5. 6PGDH is generally considered to catalyze the following reactions with the generation of NADPH: 6-phosphogluconate + NADP⁺ → ribulose 5-phosphate + CO₂ + NADPH. That is, the PP pathway was more active when the strain was cultured at pH 3. Transketolase (spot 21) is an important enzyme in the pentose phosphate cycle and reduced pentose phosphate cycle, with pyrophosphate thiamine and Mg²⁺ as the prosthetic group. Triose phosphate isomerase (spot 10), which catalyzes triose phosphate isomer to transform between dihydroxyacetone phosphate and type D glyceraldehyde 3-phosphate, plays an important role in the glycolysis process and energy supply. However, the expression of triose phosphate isomerase was down-regulated at pH 5. Adenylate kinase (spot 19) is an important enzyme in energy metabolism, which catalyzes adenosine triphosphate (ATP) to make adenosine monophosphate (AMP) and adenosine diphosphate (ADP) by phosphorylation. Herein, two proteins involved in energy metabolism were up-regulated when cultured at a pH value of 5: phosphopyruvate hydratase and amino acid transporter ATP-binding subunit. Phosphopyruvate hydratase (spot 24), which is involved in the process of sugar dysplasia catalytic-D-2-phosphoric acid by glycolysis glyceric acid (PGA)-enol phosphate type adverse reactions of pyruvate (PEP), transform PEP to PGA, it plays an important role in the process of energy metabolism in cells.³⁷ Adenosine phosphate protein subunits (spot 18) are involved in the process of generation of biological energy, and dipeptide adenosine phosphate is involved in the synthesis of dTDP-4-ethyl amide group- α -D-trehalose (dTDP-*N*-acetylthomosamine) in *Haemophilus parasuis*; the results are presented in Uniprot. Under the acidic conditions, a part of the proteins involved in energy metabolism was up-regulated, and other was down-regulated in the strain X9-4.

6PGDH (spot 25) in the process of metabolism in the PP pathway produces a substance called NADPH, which can protect cells from oxidation. Thus, 6PGDH is involved in energy metabolism and can cause stress. Aldehyde dehydrogenase (spot 23) plays an important role in improving the resistance of organisms. Guo *et al.* showed that under a low-temperature stress, genetically modified (SoBADH gene) strain exhibits high aldehyde dehydrogenase activity and significant improvement in frost-resistance ability.³⁸ There were also differentially expressed proteins, such as 70 kDa heat stress protein (spot 3), related to the immune response.

The toxin needs to be discharged by the translocator after its production. The expression of glutathione S-transferases³⁹ (GSTs, spot 8) was up-regulated under the culture condition of pH 5. GSTs are a set of multifunctional isozymes widely distributed in various organisms, and their function involves coupling the electrophilic group of substances with the mercapto group of reduced glutathione; this makes it easy for the substances to cross the cell membranes by increasing their hydrophobicity. It was observed that there was positive correlation between up-regulated enzymes of GSTs and the efficiency of OTA production, the concentration of OTA in *P. citrinum* was increased when the expression of GSTs was up-regulation. ABC transporters (spot 9) is a type of protein across the membrane, which widely exists in various organisms in the range from

bacteria to humans. Its main function is to transfer the substrate combined with it outside the cell using ATP. SAM (Sterile Alpha Motif) function domain (spot 12), which is up-regulated under the culture condition of pH 5, is a protein interaction between protein models, for example, SAM functional domains at the C terminal of p63 and p73 work by recruiting other protein effectors to regulate the functions of p63 and p73.

3.4 Relative expression of the genes involved in OTA biosynthesis in response to different pH conditions

Via sequencing, the large-scale transcriptome data were obtained from *P. citrinum* (Table 2), and there was a total of 9.91 Gb clean and high-quality sequences, which were suitable for subsequent analysis.

There were different gene expressions at different time and space phases; external stimulus and internal environment also affected gene expression. Differentially expressed genes (DEGs) are the genes differently expressed under two different conditions (*e.g.*, control and processing, wild type and mutant type, different time, different organizations, *etc.*). In this study, the difference in OTA synthesis ability may be caused by differences in gene expression; therefore, it is essential to study the differently expressed unigenes of *P. citrinum* cultured at pH 3 and 5. By comparing the results, we found 2200 DEGs between two samples (fold change ≥ 2 and FDR < 0.05); among them, 1024 genes were up-regulated and 1176 were down-regulated. P3_vs_P5 were used to categorize differentially expressed genes; henceforth, up-regulated genes have a higher expression level in the sample group P5 than that in the sample group P3 and *vice versa*.

Fig. 3 Functional classification of differentially expressed protein spots.

Table 2 Statistic results of sequencing^a

Samples	Clean reads	Clean data	GC content	% $\geq Q_{30}$
pH 3	21089411	5272352750	50.32	94.27
pH 5	18568067	4642016750	50.53	94.6

^a % $\geq Q_{30}$: the percentage of bases that clean data quality value is greater than or equal to 30.

To analyze the function of these differentially expressed genes, we performed the GO and COG annotations and classification (Fig. 4). We divided 4545 unigenes into three GO function categories, which were further divided into 57 categories; many unigenes were assigned to different categories simultaneously. Then, the percent of DEG unigenes from each category was calculated. From the results of “biological process” category, the highest category of differentially expressed unigenes was “metabolism” of 1002 (12.28%); the differentially expressed unigenes in “Molecular function” category was “catalytic activity” of 822 (12.61% of gaia category), and the “combination”, 623 (11.91%); the two high percentage

categories of “cells” category were “cell part” (582, 10.39%) and “cell” (579, 10.42%). These results suggest that the difference in OTA production by *P. citrinum* may be due to the several differentially expressed genes in the categories, and differentially expressed genes in these categories accounted for a big proportion; this provides the direction for the subsequent analysis.

Regarding the transcriptome data for *P. citrinum* cultured at different pH values, it was observed that the acidic pH inhibited the toxin synthesis due to the low expression of some metabolic pathway-related enzymes. Additionally, the expression levels of some genes involved in the regulation of the biosynthesis of toxins were inhibited in *P. citrinum* cultured under an acidic environment; this could also reduce the synthesis of toxins. The DEGs were classified in the most enriched categories including amino acid transport and metabolism, transport and metabolism of carbohydrates, inorganic ion transport and metabolism, biosynthesis of secondary metabolites, and energy and supply metabolism. These differentially expressed genes are likely to be involved in the synthesis and OTA regulation process.

Table 3 Primers used for RT-qPCR in gene expression assay

No.	Unigenes	Description	Forward primer (5' to 3')	Revers primer (5' to 3')	Relative expression
1	TRINITY_DN4069_c0_g1	Acetyltransferase	GGCTCCTCAACCAACCTC	TCTCCCAATCCCTTTACC	+1.28
2	TRINITY_DN5955_c0_g3	Polyketide synthase phosphopantetheine-binding domain	AATCGTGTAACAACCATCCG	GGCTTCCATTCCAAACTC	+1.6
3	TRINITY_DN1510_c0_g1	Acyl-CoA dehydrogenase oxidase	GTAATGCCGTCGCAAGAT	GATTCGGTTCAAAGGGTT	+1.71
4	TRINITY_DN3456_c0_g2	Alcohol oxidase	TTCGTGTACTTGTCCATT	TATCGTCCGCTGCCTTCT	+3.73
5	TRINITY_DN10315_c0_g1	NAD(P)-binding protein	CTCAGAAGCACCATT	CAACATCCAACCCGTCCA	+6.29
6	TRINITY_DN9885_c0_g1	Acetylxylan esterase	TACATCGGTGCTTCTTCGTC	TCGGTGCCATAGCCTTGA	+8.04
7	TRINITY_DN526_c0_g2	Cytochrome P450	TATCCCAAGCCCATACCATC	CACCCTCTTCTCCAACG	+8.15
8	TRINITY_DN4980_c0_g4	ABC transporter, putative	TCTTCCAGGTTCTATTCGG	CTGCTCGTTGGTTCGTCT	+1.51
9	TRINITY_DN598_c0_g1	Glutathione S-transferase	GAGTTTTGGATAAGTGTTG	TTTGAAGTATTCTATGGTGG	+1.40
10	TRINITY_DN6150_c0_g1	Transketolase C-terminal domain	GCCGACTATGTCTTTCCG	ACCGTGGCATTACTACCC	+1.02
11	TRINITY_DN1616_c0_g1	Alcohol dehydrogenase	TGGCTGCGATTACACCTT	CCCTTGATACCACCGAAA	-7.81
12	TRINITY_DN2593_c0_g1	Transaldolase	CGCTTGGCTGTCCAGATA	CTTGATAGCGATGCGTGT	-6.09
13	TRINITY_DN6090_c0_g2	Beta-ketoacyl synthase domain-containing protein	TAGGACGCTGGAGTGCTTCTGGT	CTCGACGGGCTGAGTTGT	-4.55
14	TRINITY_DN6972_c0_g2	Heat shock 70 kDa protein	AGTGTGTGGGGTTTCAT	CTCCTGTGTGGGTGTGTT	-1.65
15	TRINITY_DN4080_c0_g2	Actin binding	CGAACAGGACAACGCAGC	CCACTGTCTGAAGGACGAAC	+1.019

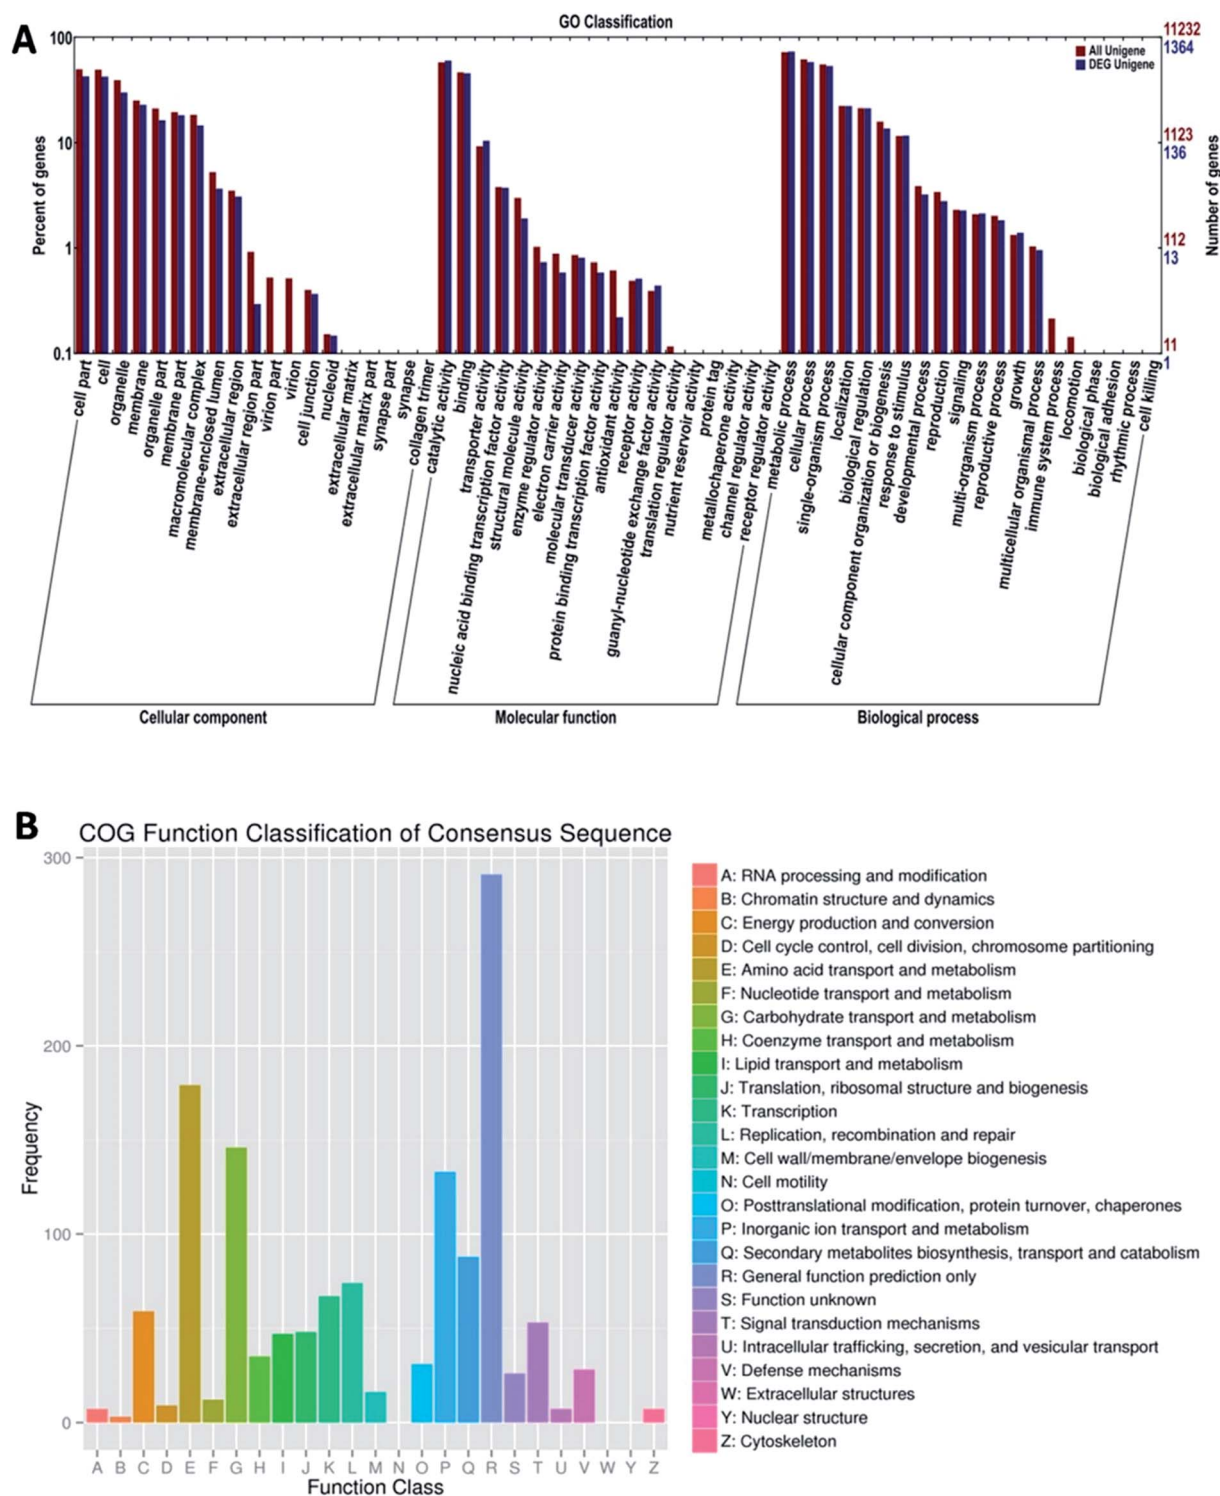

Fig. 4 Functional classification of DEG in *P. citrinum*. (A) GO classification. (B) COG classification.

To verify the differences in these genes expressed in the OTA synthesis, the mRNA levels of 14 unigenes, which were differently expressed genes and associated with toxin production, were analyzed by RT-qPCR (Fig. 5). From the results of *P. citrinum* cultured at pH 5, the expression levels of these genes were obviously higher than those of the strain cultured at pH 3. These

results were consistent with those of transcriptome data analysis.

In conclusion, the results indicated that low pH conditions inhibited the biosynthesis of OTA in *P. citrinum*. The proteomics technique employed to investigate differentially expressed proteins of *P. citrinum* under different pH culture conditions

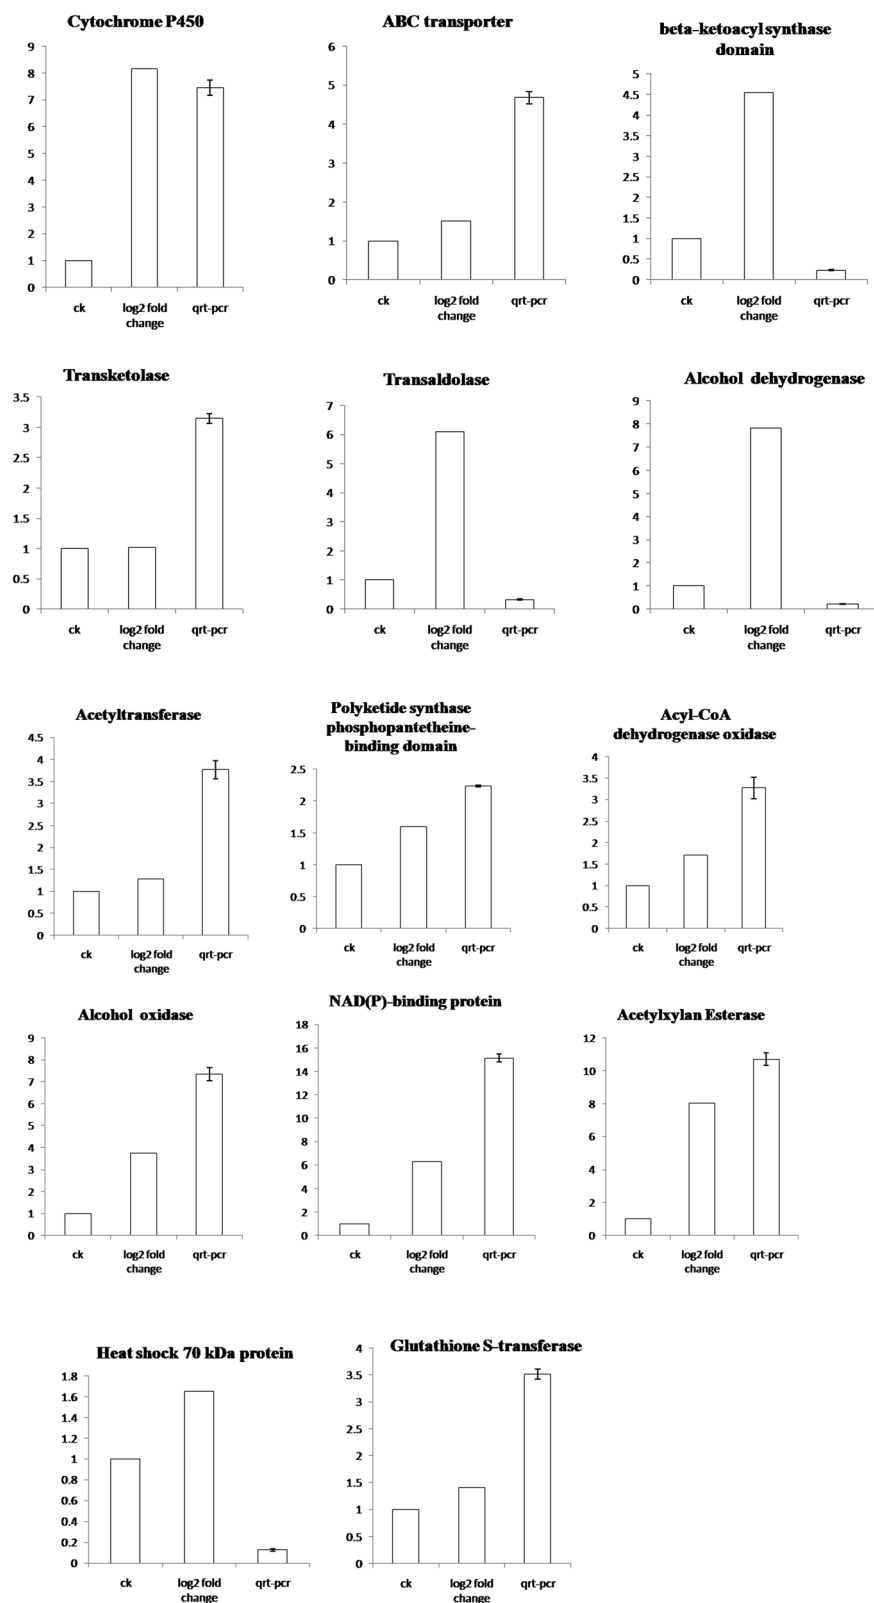

Fig. 5 Verification of differentially expressed genes by RT-qPCR. CK: *P. citrinum* cultured at pH 3. Values are means of two independent experiments. Error bars represent the standard error of the mean.

revealed that the expression levels of 11 proteins, accounting for 44% of the total number of proteins, were up-regulated in the medium of pH 5 as compared to those at pH 3. In contrast, the expression levels of most basic metabolism- and synthesis-related proteins, as well as of those related to energy supply, were decreased; this made it difficult for cells to maintain the life activities. Fructose-diphosphate aldolase, acetone phosphate acid hydratase, adenosine phosphate subunits, and glutathione S-transferase activities were decreased under the low pH (3) culture condition of *P. citrinum*. Fructose-diphosphate aldolase provides ATP and substrate for organisms, and glutathione S-transferase may be associated with toxin transport. Under the low pH (3) condition, the expression levels of fructose-diphosphate aldolase and glutathione were limited, whereas those of the stress-related proteins, such as some signal transduction and dehydrogenase-related proteins, increased. The expression level of glucose-6-phosphate dehydrogenase was increased under low pH (3) conditions; this protected the strain from stress.

Through the analysis of the transcriptome data of *P. citrinum* cultured under different pH conditions, the mechanism of OTA biosynthesis and metabolic regulation has been revealed. Under the two pH conditions of 3 and 5, 19 598 unigenes were identified. The results indicated that some genes played important roles in OTA synthesis by *P. citrinum*. These genes mainly encoded acetyltransferase, polyketone synthase phosphate generic acyl cysteamine-combined domain, acyl coenzyme A oxidase, alcohol oxidase, NAD(P)-binding protein, acetyl xylan esterase, cytochrome P450, ABC transporters, beta ketone enzyme domain protein, turn ketol enzyme, aldol enzyme, and alcohol dehydrogenase. Some proteins were consistent with the results of the two-dimensional technique; however, many important enzymes could not be identified by this technique due to technical reasons. These transcriptome findings provided the basis for the molecular level for further studies of OTA biosynthesis by *P. citrinum* and *Penicillium* species. Finally, the transcriptome data for *P. citrinum* not only revealed the possible mechanism of OTA synthesis and molecular regulation in *P. citrinum*, but also provided scientific guidance for controlling the OTA synthesis.

Ethical statement

This article does not contain any studies with human participants or animals performed by any of the authors.

Conflicts of interest

The authors declare that they have no conflict of interest.
