Magnetic solid phase extraction based on graphene oxide/nanoscale zero-valent iron for the determination of tetracyclines in water and milk by using HPLC-MS/MS†

Dan Wei, a Shuchao Wu* b and Yan Zhu *a

A magnetic solid-phase extraction (MSPE) based on graphene oxide/nanoscale zero-valent iron (GO/nZVI) coupled with high performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS) was proposed for the determination of trace tetracycline antibiotics (TCs) in water and milk. GO covered nZVI was self-assembled by electrostatic forces by varying the pH. Several important parameters affecting the MSPE procedure have been investigated. The pH value is a key factor in the whole MSPE process. An appropriate pH can not only improve adsorption and desorption efficiency, but also enable the extraction of TCs from GO/nZVI by using deionized water. Optimal conditions were then used for the extraction of TCs from real samples, prior to HPLC-MS/MS determination in the positive ESI mode of multiple reaction monitoring (MRM) using a ZORBAX Eclipse Plus C18 column. The proposed method achieved low limits of quantitation in the range of 8.05–83.19 ng L⁻¹ and 17.42–182.75 ng L⁻¹ for water and milk samples, respectively, and satisfactory recoveries in the range of 84.2–105.5% with intra-day RSD in the range of 0.6–2.5% and inter-day RSD in the range of 1.2–9.2% for the spiked water sample and from 87.0% to 101.8% with intra-day RSD in the range of 1.1–5.4% and inter-day RSD in the range of 2.0–9.7% for the spiked milk sample.

1. Introduction

Tetracyclines (TCs) are broad-spectrum antibiotics against infections caused by Gram positive,1 Gram negative bacteria,2 chlamydia, mycoplasmas, rickettsiae and protozoan parasites.3,4 Accordingly, TCs have been widely used in human and veterinary medicine and have been reported as one of the most intensely used antibiotics in the European Union.4 However, improper use of TCs, especially when overused, may lead to unsafe residue levels in different animal tissues and animal-producing food intended for human consumption,5 which can produce a significant threat to human health, including allergic reactions, toxic effects, damage to the liver, yellowing of teeth and gastrointestinal disturbance. Besides, the release of animal excrement with excessive TC residues into the environment can also lead to water pollution and soil contamination.6 Therefore, it is particularly necessary to develop an effective and reliable analytical method for the determination of trace level TCs in complex matrices.

† Electronic supplementary information (ESI) available. See DOI: 10.1039/c7ra08203g

During recent years, several analytical methods have been developed for the determination of veterinary drugs residues in different matrices, including chemiluminescence,7–10 microbiological assays,11 capillary electrophoresis12 and high performance liquid chromatography (HPLC).13–17 HPLC with different detectors is the most commonly used techniques and has a great advantage in analyzing non-volatile and thermally labile compound.18–22 Analysis of TCs is performed mainly by HPLC with various detection techniques, including diode-array23 or single UV,18 electrochemical detection,19 fluorescence detection20,21 and mass spectrometric detection.22 Due to its high sensitivity and selectivity, HPLC coupled to mass spectrometry (MS) or tandem mass spectrometry (MS/MS)23–26 is becoming more commonly used in the analysis of TCs in very complex samples such as milk, waste water and animal tissues. MS detection with high sensitivity and accurate quantification is the method selected in this study. Because the sample matrices are complex and the concentration of target analytes is very low, direct analysis of sample is difficult and generally a sample processes are indispensable. Sample pretreatment techniques widely used for the isolation of TCs from milk and water samples include liquid–liquid extraction (LLE)27–29 and solid-phase extraction (SPE).27–29 Solid phase extraction is well developed sample pre-concentration technique in recent years with good merits such as simplicity, high sensitivity, low
2. Experimental

2.1. Reagents and materials

Graphene oxide (GO) with purity greater than 99% was obtained from Nanjing Xinfeng Nanomaterials Technology co., LTD (Nanjing, China). Zero-valent iron (nZVI) was supplied from Shenzhen micro-nano Science and Technology co., LTD (Shenzhen, China). Acetonitrile (ACN) and methanol (MeOH) with HPLC grade were obtained from Sigma-Aldrich (Shanghai, China). Dichloromethane (DCM) with analytical grade was supplied from Shanghai Shuanglin Chemicals Corporation (Shanghai, China). Acetic acid (HAc) with analytical grade was obtained from Shanghai Lingfeng Organic Chemicals Co., Ltd. (Shanghai, China). Ammonium hydroxide (NH4Ac) and sodium chloride (NaCl) with analytical grade were obtained from Hangzhou Longshan Fine Chemicals Co., Ltd. (Hangzhou, China).

4-Epitetracycline (ETC), oxytetracycline (OTC), tetracycline (TC), anhydrotetracycline (ATC), demectocycline (DMC), and chlortetracycline (CTC), all with purity greater than 95%, were obtained from Sigma-Aldrich (Shanghai, China). The different standard solutions were prepared daily by dilution of a stock solution of each TC at a concentration of 1000 mg L\(^{-1}\), which were prepared by dissolving the pure substances in methanol. These solutions were refrigerated in the dark at 4 °C. Lower concentration standard solutions were prepared daily in the dark by appropriate dilutions using deionized water from their stock solutions.

The deionized water employed in all experiments was obtained from a Millipore-Milli-Q water system (Millipore, Milford, MA, USA), with resistivity not lower than 18.2 M\(\Omega\) cm. GO solution at a concentration of 1 mg mL\(^{-1}\) was prepared by dispersing GO in deionized water with sonication for 15 min. All optimized studies were performed using the uncontaminated underground water samples spiked with 10 ng mL\(^{-1}\) of the six TCs, which were used as the fortified samples.

2.2. Samples and sample preparation

Two kinds of milk samples: a pasteurized whole milk sample and a skimmed milk sample (fat content <0.5% w/w) were supplied from local market (Hangzhou, China). Milk samples were kept at 4 °C until use. 10.0 mL milk sample was weighted and a skimmed milk sample (fat content <0.5% w/w) were prepared. 10.0 mL milk sample was weighted into an Eppendorf vial (50 mL), and appropriate volumes of TCs standards were added to the vial. Then the sample was dissolved in 10 mL of 10 mmol L\(^{-1}\) NH4Ac. After centrifugation (10 000 rpm, 5 min), the supernatant was adjusted to pH 7.0 with HAc and NH4H2O.

Four water samples: tap water, waste water, West Lake water and Qiantang River water were collected in Hangzhou, China. Each sample was filtered through a 0.45 µm membrane before analysis. Deionized water samples spiked with appropriate volumes of TCs stock solution were used for the method optimization and validation experiments.

2.3. Apparatus and chromatographic conditions

Fourier transform infrared (FT-IR) spectra (4000–500 cm\(^{-1}\)) in KBr were recorded on a Tensor 27 spectrometer (Bruker,
Germany). The morphological analysis of the magnetic adsorbents was performed using an S-4700 scanning electron microscope (SEM) instrument (Hitachi, Japan). The pH values were controlled with a Seven Easy S30 pH meter (Mettler Toledo Instruments Co. Ltd., Shanghai, China).

The chromatographic analysis was performed on an Agilent 1290 infinity (Agilent, USA) equipped with an auto sampler controlled the gradient system. The analytical column was ZORBAX Eclipse Plus C18 (3.0 mm × 100 mm, 1.8 μm, Agilent, USA) operated at 35 °C; the mobile phase for the chromatographic separation was a mixture of A (100% ACN) and B (deionized water and 1% (v/v) HAc). Separation was performed in the following gradient conditions: 0 min, 10% A, to 30% A at 10 min, to 100% A at 11 min, to 10% A at 14 min and maintained for 3 min. Finally, the column was re-equilibrated for 5 min with the initial composition of the mobile phase.

Detection and quantification were carried out using 6460 Triple quadruple mass spectrometer equipped with ESI ion source (Agilent, USA). Data acquisition parameters (i.e. fragment voltage, collision energy) were optimized for each of TCs. Quantification of TCs was performed in the positive mode of multiple reaction monitoring (MRM). The temperature of the drying gas and sheath gas were 300 °C, 250 °C, respectively. The flow rate of the drying gas, sheath gas was 5 L min⁻¹, 10 L min⁻¹, respectively. A nebulizer pressure was set at 45 psi. Capillary voltage and nozzle voltage were set at 3500 V and 1000 V. The drying gas, sheath gas and nebulizer gas were high pure nitrogen.

2.4. Preparation of the magnetic adsorbent

The GO/nZVI particles were prepared according to the method reported by Liu et al. (2016). Briefly, nZVI was dissolved in 10 mL deionized water and sonicated for 15 min at 25 °C. When nZVI was dispersed in deionized water, the GO solution (1 mg mL⁻¹) was added with vortex stirring for 30 s and the black magnetite precipitates were formed. Then, magnetite precipitates (GO/nZVI) was magnetically isolated and washed with deionized water twice in an ultrasonic bath, and the supernatant was discarded. After that, GO/nZVI was stored in deionized water at room temperature in the dark for further use.

2.5. MSPE procedure

The MSPE procedure is shown in Fig. 1. The extraction method was performed as follows: firstly, 15 mg magnetic adsorbent GO/nZVI was added into a beaker. Then, 10 mL portion of the standard or sample solution containing 10 μg L⁻¹ of ETC, OTC, TC, ATC, DMC, and CTC was transferred into a beaker. To avoid degradation of TCs and self-disassembly of GO/nZVI, the solution was adjusted pH to 4.0–7.0 by adding HAc and NH₃·H₂O. Subsequently, the solution was sonicated for 10 min to facilitate adsorption of the TCs onto the GO/nZVI. Then, the magnetic adsorbent was separated by using a magnet and the supernatants were decanted directly. 1 mL of NH₃·H₂O (pH 11) solution as eluent was added and sonicated for 5 min for desorption of TCs. Finally, desorption solution was evaporated to dryness under a mild nitrogen gas stream, and the dry residue was redissolved in 200 μL of ultrapure water. 10 μL of the solution was injected into the HPLC-MS system for subsequent analysis.

3. Results and discussion

3.1. Optimization of HPLC-MS/MS conditions

The development process of the HPLC-MS/MS method began with investigation of chromatographic separation, gradient elution and the effects of the ration and the composition of both solvent A and solvent B on chromatographic separation. The results indicated that mobile phase A (100% ACN), mobile phase B (water with 1% (v/v) HAc) are highly suitable as a mobile
phase system for the separation of the TCs by gradient elution as follows: 0 min, 10% A, to 30% A at 10 min, to 100% A at 11 min, to 10% A at 14 min and maintained for 3 min. Then, the parameters for mass spectrometry optimization were investigated. Capillary, fragmenting voltage and collision energy were optimized to obtain the characteristic MRM ion pairs that could be used as the basis for quantitative analysis. MRM mode was determined by selecting the precursor ion \( m/z \) and one of its daughter ion \( m/z \) with high specificity and sensitivity as quantitative ion. Optimal fragmenting voltage and collision energies varied for each TC (Table 1). MRM spectra for the mixture of six TCs standard and fragmentation spectra with their product ions structures are shown in Fig. S1† and 2.

### 3.2. Characterization of GO/nZVI

The morphology of GO/nZVI was studied by SEM. GO/nZVI (previously dried at 100 °C, 24 h) was aggregated as clusters, forming a fluffy structure with an average diameter of about 100–500 nm (Fig. S2†). The SEM image of GO/nZVI was agreed with the reported method. Furthermore, the composition of GO/nZVI was examined by FT-IR. The characteristic absorption peaks of GO, that is, 1725 cm\(^{-1}\) (C=O), 1224 cm\(^{-1}\) (C\(\equiv\)O\(\equiv\)C), and 1042 cm\(^{-1}\) (C=O), were not observed in FT-IR spectrum (Fig. S3†), indicating GO well combined with nZVI.

### 3.3. Optimization of magnetic solid-phase extraction procedure

In order to select the optimum magnetic solid phase extraction conditions for the extraction of the TCs, 10 mL of six TCs spiked sample at each concentration of 20.0 \( \mu \)g L\(^{-1}\) was used to study the extraction performance of the magnetic absorbent GO/nZVI under different experimental conditions. All of the experiments were performed in triplicate and the means of the results were used for optimization.

#### 3.3.1. Effect of the amount of adsorbents.

To achieve good recovery of TCs, the amount of GO/nZVI was varied from 1 to 30 mg. As shown in Fig. 3a, the extraction recoveries of the six TCs were increased with increasing the sorbent amount from 1 to 15 mg and then remain constant up to 30 mg. Thus 15 mg was chosen for further experiments.

#### 3.3.2. Effect of the extraction time.

Optimization of extraction time was performed by increasing the ultrasonic time from 2 to 30 min. Fig. 3b shows that the extraction recoveries greatly increased from 2 to 10 min, and subsequently almost remained invariant with extraction time increasing, indicating

</table>
the adsorption equilibrium could be achieved in 10 min. Thus, 10 min was selected as the extraction time.

3.3.3. Effect of the sample pH. The pH of the sample solution has an important influence on the MSPE process. It is reported that the major interaction between the adsorbent and the TC is electrostatic interaction, so an appropriate pH not only can form the adsorbent self-assembly, but also can enhance extraction efficiency. Accordingly, TCs are amphoteric compounds whose molecular state is influenced by pH and would suffer from hydrolysis in strong acid and alkaline conditions, especially when the pH is less than 2 and more than 12. GO/nZVI is based on the pH-responsive and magnetically separable dynamic system. The pH value in the range of 2 to 12 under their cationic, neutral or anionic forms was investigated. In addition, the GO/nZVI is fabricated on acid and neutral conditions. The highest recoveries were obtained in the pH range between 2 and 7, in which TCs are in cationic or neutral forms. It reported that the estimated zero point of charge (ZPC) of GO and nZVI were pH 2 and pH 9, respectively. Therefore, GO/nZVI can be easily self-assembled and absorb TCs via electrostatic attractive forces (Fig. 3c). Apparently, there was a decrease in the recovery of TCs at pH less or higher than 7. Maybe with increasing solution pH higher than 7 or in the range of 2 to 7, the electrostatic...
repulsive force increased or GO/nZVI can be disassembled and therefore slightly inhibited TCs adsorption resulting in recovery decrease. Thus, pH 7.0 was selected for the following experiments.

3.3.4. Desorption conditions. To select the best for desorbing TCs from GO/nZVI, MeOH, ACN, CHCl₃, and deionized water were studied. Fig. 3d showed that best elution of TCs with lowest matrix interferences could be attained using deionized water. Therefore, deionized water was chosen as the optimal elution.

An important effect of elution pH (4–13) on the recovery was also studied. As showed in Fig. 3e, slightly increased recoveries was observed by using deionized water with pH in the range of 9 to 11, slight decrease was observed with pH over 11. As a result, pH 11 was chosen to ensure sufficient desorption of the TCs.

Optimization of elution volume was studied in the range of 1.0 to 5.0 mL. As showed in Fig. 3f, the satisfactory recoveries were obtained using 1.0 mL of deionized water (pH 11). Thus, 1.0 mL was used in this study.

In order to speed up the transfer of TCs, GO/nZVI containing TCs was subjected to sonication during each elution step. The sonication time (1–10 min) was also examined. The results indicate that 5 min was enough for the TCs desorption. Finally, 5 min sonication time was adopted.

3.4 Reusability studies

One of the critical factors for evaluating the performance of the adsorbent is the regeneration of the magnetic materials after use. In order to investigate the reusability of GO/nZVI sorbent, the adsorbent was washed with ultrapure water and MeOH, and then reused for more than ten times. It turned out that the GO/nZVI had an acceptable reusability without a significant loss of sorption capacity.
3.6. Application to real samples

Under the optimized conditions, the newly proposed GO/nZVI-based MSPE coupled with HPLC-MS/MS technique was applied for determination of the six target analytes (ETC, OTC, TC, ATC, DMC, and CTC) in four water samples (tap water, waste water, West Lake water and Qiantang River water collected from Hangzhou, China) and two kinds of milk samples (a pasteurized whole milk sample and a skimmed milk sample from local market in Hangzhou, China). The results showed that six TCs residue were not detected in any of these samples.

3.7. Method comparison

The performance of the proposed method was compared with other reported methods for tetracycline residue detection in terms of detection techniques, linear range, LOD, recovery, and RSDs. The results were summarized in Table 4. As can be obviously seen from table, our newly developed MSPE method could achieve desirable recoveries and a wide linearity range, which were superior to or comparable with other listed methods. Moreover, by virtue of sensitive detection technique and effective extraction mode, our present method could provide a lower LODs and RSDs compared with other reported methods. Furthermore, the most previous reported methods employing SPE were more complicated than the present MSPE method. The adsorbents used directly or packed in SPE cartridges can also bring in an additional part of expense and extra risk of pollution to the environment. In addition to the common MSPE advantages of no need of additional centrifugation or filtration, the newly developed pH-responsive self-assembled MSPE procedure exhibits easy preparation, high extraction efficiency, easily separable and high reusability at low cost of toxic organic solvent by varying pH value of aqueous solution, which is economical and environment-friendly and makes it a promising method for analysis of water and milk samples with low concentration TCs residues. Therefore, the method developed in this study is sensitive, accuracy economical and environment-friendly for analysis of trace TCs.

4. Conclusion

In this study, the newly pH-responsive self-assembled MSPE method with HPLC-MS/MS in the ESI positive mode was applied to determination of six TCs from water and milk samples. With the appropriate adjustment of pH, the magnetic absorbent GO/nZVI can be self-assembled in the ultra water solution and showed high extraction efficiencies for TCs residues using the deionized water. Without use of organic extraction solvent, good linearity, low LOD, satisfactory spiked recoveries and high sensitivity was attained for the real samples. The proposed method can be used as a convenient and reliable method for the determination of trace TCs in water and milk samples.
