Non-isothermal crystallization kinetics of ramie fiber-reinforced polylactic acid biocomposite

 Xing Jin,^a Xie Chen,^a Qian Cheng,^a Naiwen Zhang,^b Shenyang Cai^a and Jie Ren *^a

Ramie fiber (RF) reinforced polylactic acid (PLA) laminated biocomposite was prepared by hot-press molding using the non-woven ramie fibers and short PLA fibers. To understand the effect of ramie fibers on the crystallization behaviors of PLA, we study the non-isothermal crystallization kinetics of pure PLA and PLA/RF biocomposite. The crystallization behaviors of pure PLA and PLA/RF biocomposite with 40 wt% non-woven ramie fibers first were determined by differential scanning calorimetry (DSC). The results show that the addition of the RF could propel the crystallization process of PLA, during which the RF played a role in heterogeneous nucleation. Then, we used several models to analyze the crystallization behaviors during cold crystallization of PLA and PLA/RF biocomposite. The Jeziorny model for non-isothermal crystallization kinetics indicated that the crystallization process of PLA and PLA/RF biocomposite could be divided into two stages, and the addition of RF would not change the crystallization mechanism of PLA compared with that of pure PLA, which also was confirmed by the combination model of Ozawa equation and Avrami equation. In addition, the Doyle–Ozawa model's results revealed that when the relative crystallinity increased, the local apparent activation energy of PLA and PLA/RF biocomposite showed a gentle downward trend, and the average local activation energy was consistent with the apparent activation energy. In general, the addition of RF weakened the interaction between PLA chains and reduced the energy barrier of PLA in the crystallization process for the ramie fiber-reinforced PLA biocomposite.

1. Introduction

Polylactic acid (PLA) as an environmentally friendly, renewable, biodegradable polymer with good mechanical properties has been widely used in many fields, such as packaging, in disposable supplies, garments, medical devices, agriculture and automobiles.^{1–4} However, the large-scale applications of PLA are still limited by its inherent properties, such as lack of toughness, low heat deflection temperature (HDT), and low thermal stability. The weaknesses of PLA are mainly due to the slow crystallization rate of PLA. The presence of a large amount of methyl groups on the PLA backbone reduces the symmetry of polymer chains. In addition, the active oxygen atoms in carbonyl groups are prone to hydrogen bonding, thus limiting the diffusion ability of the polymer chains and leading to poor crystallization ability. Therefore, studies on crystallization mechanism of PLA will be beneficial to improve its crystallization in order to make up for the limits of PLA and broaden the application fields of PLA further. Compared with the isothermal crystallization conditions, the non-isothermal crystallization

conditions are much closer to the real industrial processing conditions of PLA, such as extrusion, and molding. During the past years, studies on the PLA crystallization have attracted great interests, particularly in the field of dynamic parameters of PLA in cold crystallization.^{5,6} However, the study on the non-isothermal crystallization kinetics of PLA in the cold crystallization process is rarely reported.

Fiber reinforcement is an effective approach for improving the mechanical properties and thermal stability of polymer materials. Natural fibers, as a type of ideal replacement for the traditional synthetic fibers, possessing outstanding mechanical properties, excellent biodegradability, low density and price, have been increasingly used as reinforcement in composites. Among them, ramie fiber (RF) is particularly prominent because it provides the best heat resistance and superior tensile strength and modulus compared to that of jute, flax, hemp, and sisal.^{7–9} Our previous studies have indicated that the green biocomposites with natural RF reinforcement and biodegradable PLA resin matrix can be prepared by adding ramie short fibers or fabrics into PLA using the two-roll mill or hot compression molding technique.^{10–13} The obtained PLA/RF biocomposites show much increased mechanical properties, such as tensile, flexural and impact strength, relative to that of pure PLA.

In addition, the natural fiber was also reported to play a role in heterogeneous nucleation in the PLA crystallization

process.^{14,15} Our recent study reveals that the addition of RF accelerates the crystallization rate of PLA and improves the thermal stability of PLA biocomposites.¹⁶ The cold crystallization temperature of PLA/RF biocomposite is slightly lower than that of neat PLA. Thus, the PLA/RF biocomposite has a quicker start of crystallization than that of neat PLA. Furthermore, the heat deflection temperature of PLA/RF biocomposites can be improved remarkably by further heat treatment.

In this study, the crystallization mechanism and crystallization activation energy of pure PLA and PLA/40 wt% non-woven ramie composites (PLA/RF) during cold crystallization were analyzed *via* Jeziorny, Avrami, Ozawa, Kissinger and other models. The effect of RF on the crystallization behaviors of PLA is discussed, as well.

2. Experimental

2.1. Materials

Ramie fiber was supplied by Jintan Jinlan Ramie Fiber Factory (Jiangsu, China). PLA short fiber (length 51 mm and linear density 6 dtex) was obtained from Shanghai Tong-Jie-Liang Biomaterials Co., Ltd. (China). The needle punched non-woven PLA (surface density 20 g m⁻²) and needle punched non-woven PLA/RF (surface density 200–300 g m⁻²) with 40 wt% ramie fiber were provided by the Textile Experiment Center of Donghua University. The preparation of non-woven PLA/RF and PLA both followed certain steps: mixing, opening, carding, cross paving and needle punching. For non-woven PLA, the needle punching thickness was about 0.2–0.5 mm, whereas for non-woven PLA/RF, it was about 1.5–2 mm. In addition, for the non-woven PLA/RF, the RF was cut into 50 mm length short pieces before use, and the weight ratio of PLA short fiber and RF was controlled to 60 : 40 before mixing. The PLA non-woven sheets were cut into desired sizes and shapes for evaluation.

2.2. Fabrication of the laminated PLA/RF biocomposite

The non-woven PLA/RF was dried in a vacuum drying oven at 60 °C for 24 h before use to ensure that all the absorbed moisture was removed. Pre-drying was to prevent void formation during the hot-press process. The multilayer non-woven

stacking and hot-press molding were applied to prepare the PLA/RF biocomposite, as shown in Scheme 1. The lay-ups were first preheated at 175 °C and 1 MPa for 10 min, hot-pressed into sheets at 5 MPa for 5 min, and then cooled to room temperature at 5 MPa. The obtained composites were cut into desired sizes and shapes for evaluation.

2.3. Differential scanning calorimetry (DSC)

DSC measurements were performed on a Q100 thermal analysis system (Tainstsh, USA). First, the PLA and PLA/RF samples were heated to 200 °C at a rate of 20 °C min⁻¹ and incubated for 3 min. Then, the samples were cooled to room temperature at a rate of 10 °C min⁻¹, followed by incubating for 1 min. After that, the samples were separately heated to 200 °C at a rate of 5 °C min⁻¹, 10 °C min⁻¹, 15 °C min⁻¹ and 20 °C min⁻¹. Experiments were carried out under nitrogen flow (30 mL min⁻¹). The weight of all samples was kept between 5 mg and 10 mg.

3. Results and discussion

3.1. Non-isothermal crystallization behaviors of PLA and PLA/RF biocomposites

DSC second heating curves of PLA and the PLA/RF biocomposite at different heating rates are shown in Fig. 1. Generally speaking, during non-isothermal crystallization of polymers, the crystallization temperature varies over time due to different heating rates, and the DSC curves fluctuate with the change of heating rates. For pure PLA, the crystallization exothermic peaks drifted toward the high temperature as the heating rate increased. When the heating rates varied from 5 °C min⁻¹ to 20 °C min⁻¹, the values of peak temperature (T_p) corresponding to the crystallization exothermic peaks of PLA were 101.0 °C, 107.1 °C, 112.4 °C and 119.3 °C. In addition, the initial or starting crystallization temperatures (T_s) of PLA were 93.4 °C, 95.6 °C, 97.2 °C and 101.8 °C. The results illustrate that the non-isothermal crystallization behavior of PLA depends significantly on the heating rate, and the increase of the heating rate leads to the retardation of crystallization initiation. The non-isothermal crystallization of the PLA/RF biocomposite was similar to that of PLA, and its T_p values increased with the increase in heating rates from 100.1 °C, to 105.9 °C, 111.8 °C, and 118.2 °C and the T_s were 92.2 °C, 94.0 °C, 96.8 °C and 98.2 °C, respectively.

On comparing the values of T_p and T_s of PLA and PLA/RF biocomposites, it can be found that the addition of RF accelerates the crystallization process of PLA, which is related to the interaction between polymer chains. For the pure PLA system, the interaction between the polymer chains is strong, and the energy barrier required to overcome in the formation of ordered lattice is also large. However, the addition of RF destroys the tight contact between the PLA chains and enhances the activity capacity of polymer chain segments, thus making the formation of crystals easier.

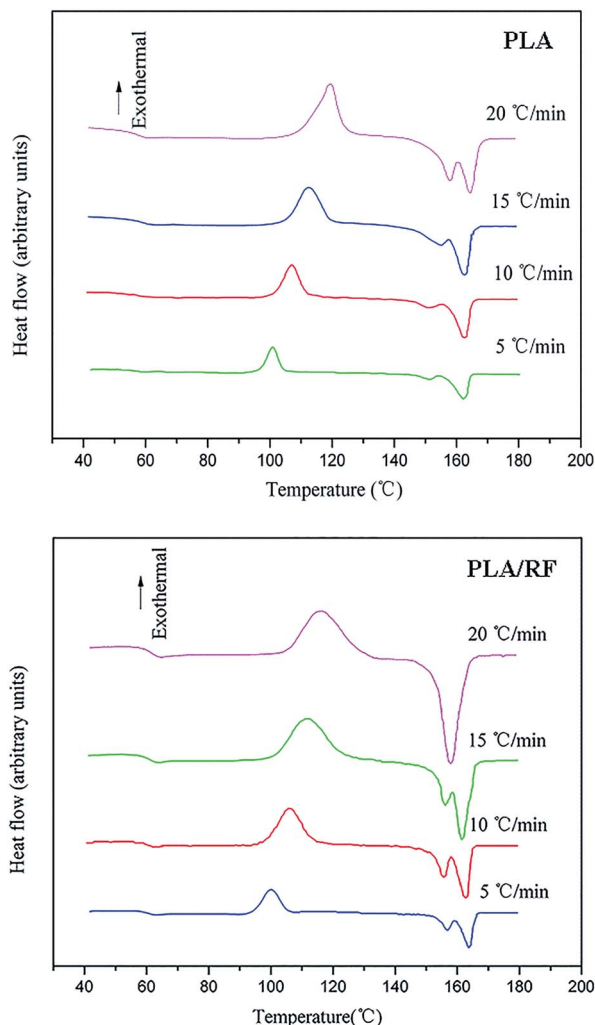

Fig. 1 DSC second heating curves of PLA and PLA/RF biocomposite at different heating rates.

3.2. The crystallization mechanism of the PLA and PLA/RF biocomposites

Fig. 2 shows crystallized fraction percentage over time at different heating rates of PLA and PLA/RF biocomposites. In the study of the crystallization mechanism of the materials, the Johnson–Mehl–Avrami (JMA) equation^{17,18} is usually applied for quantitative analysis. However, the JMA equation is an analytical method in the isothermal crystallization process, and it is not applicable for non-isothermal crystallization. Afterwards, Jeziorny¹⁹ successfully modified and applied the JMA equation to the non-isothermal crystallization process.

Avrami equation is shown in eqn (1):

$$1 - x = \exp(-Z_c t^n) \quad (1)$$

On taking logarithm on both sides of the eqn (1), we get eqn (2):

$$\lg[-\ln(1 - x)] = n \lg t + \lg Z_c \quad (2)$$

Fig. 2 Crystallized fraction percentage of pure PLA and PLA/RF biocomposites as a function of time at different heating rates.

here, n is the Avrami constant, where its value depends on crystallization mechanism and crystal structure; Z_c is the crystallization rate constant and characterizes the rate parameters of nucleation and growth during crystallization process; x is the percentage of crystallization over time.

The Jeziorny model takes the heating rate as the correction value of the crystallization rate constant, and the modified expression is eqn (3):

$$\lg Z_c = \frac{\lg Z_c}{\beta} \quad (3)$$

here, Z_c is the corrected crystallization rate constant, and β is the constant heating rate.

Therefore, the Avrami constant (n) and the crystallization rate constant (Z_c) can be obtained *via* the slope and intercept by the linear fitting method ($\lg[-\ln(1 - x)]$ vs. $\lg t$, as shown in Fig. 3) and in conjunction with the curve of relative crystallinity over time of PLA and PLA/RF biocomposites, as displayed in Table 1.

As shown in Fig. 3, each fitting curve can be roughly divided into two stages with different slopes, which is called an initial stage and subsequent stage. The inflection points of the curves occur when the relative crystallinity of the samples is approximately 80%. The deviation phenomenon of the fitting curve is also reported in other literature.^{20,21} The fitting lines are roughly

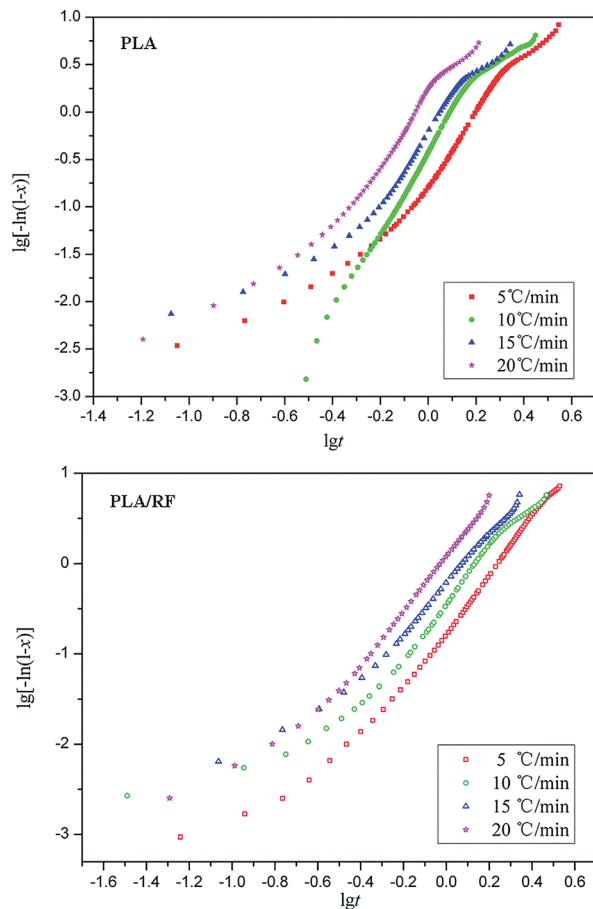

Fig. 3 The $\lg[-\ln(1-x)]$ vs. $\lg t$ diagram for PLA and PLA/RF at different heating rates.

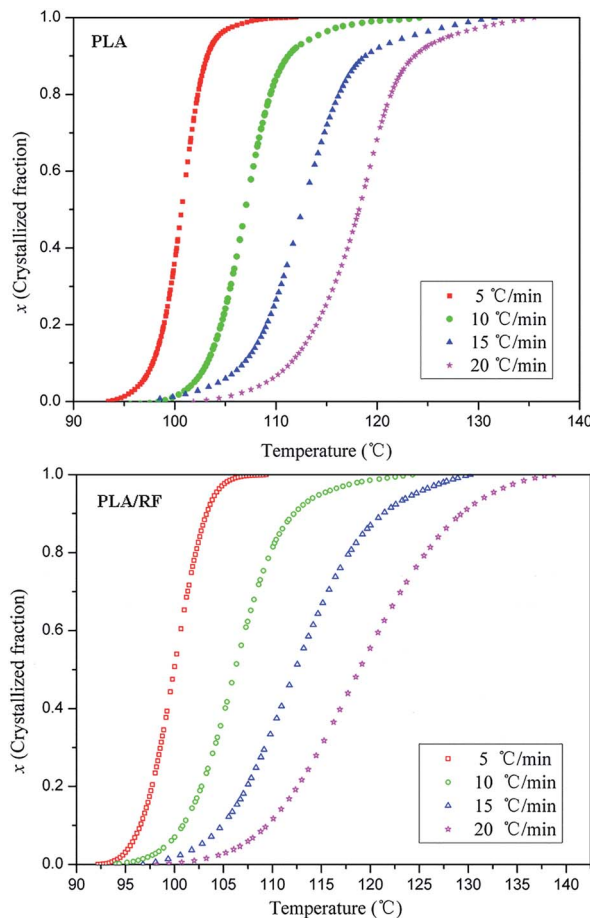

Fig. 4 Crystallized fraction percentage of PLA and PLA/RF bio-composites as a function of temperature at different heating rates.

parallel with each other at each stage of the curve, and the fitting straight line is shifted to the direction of time decreasing as the heating rate increases, which means that the crystal nucleation mechanism and growth morphology of PLA and PLA/RF are similar at different heating rates.

For PLA, the average Avrami constant of the initial phase (n_1) is 3.72, whereas that of the subsequent phase (n_2) is 1.8. The Avrami constant is a constant based on the crystallization mechanism.²² The above data indicate that the crystallization mechanisms of PLA in the initial and subsequent stages are

different, and the dynamics of the crystal growth mechanism transformation comes from the spherulitic collision.²³

During the initial stage, the number of complete spherulites in the material system is small, resulting in a lower nucleation rate. When the relative crystallinity reaches to about 80%, the crystallization enters the subsequent stage, and the Avrami constant decreases significantly. This is because the growth of the crystal at this stage is the diffusion control type that is not conducive to secondary crystallization. Because the nucleation rate of the subsequent stage is low and the crystallization is not sufficient, it is easy for PLA products to continue crystallization in practical use and result in a change in product performance. Therefore, in order to obtain better performance and stable products, an annealing process is often applied in the follow-up process. The heat treatment process can promote secondary crystallization and maximize the degree of crystallization. For the PLA/RF biocomposite, the average Avrami constants n_1 and n_2 are 3.21 and 2.39 in the initial and subsequent stages, respectively. Therefore, the addition of RF does not change the crystallization mechanism of PLA. As can be seen from Table 1, the increase in the heating rate can enhance the crystallization rate to a certain extent, and the addition of RF has little effect on the crystallization rate.

Table 1 Dynamic parameters of the PLA and PLA/RF biocomposites

	β ($^{\circ}\text{C min}^{-1}$)	Primary stage		Secondary stage	
		n_1	Z_{c1}	n_2	Z_{c2}
PLA	5	3.55	0.713	1.89	0.928
	10	4.31	0.908	1.66	1.009
	15	3.68	0.969	1.76	1.011
	20	3.35	1.018	1.94	1.033
PLA/RF	5	2.93	0.716	2.68	0.779
	10	3.56	0.907	1.75	0.980
	15	2.92	0.963	2.20	0.984
	20	3.43	1.009	2.92	1.010

Fig. 5 The $\lg[-\ln(1-x)]$ vs. $\lg \beta$ diagram for PLA and PLA/RF biocomposites.

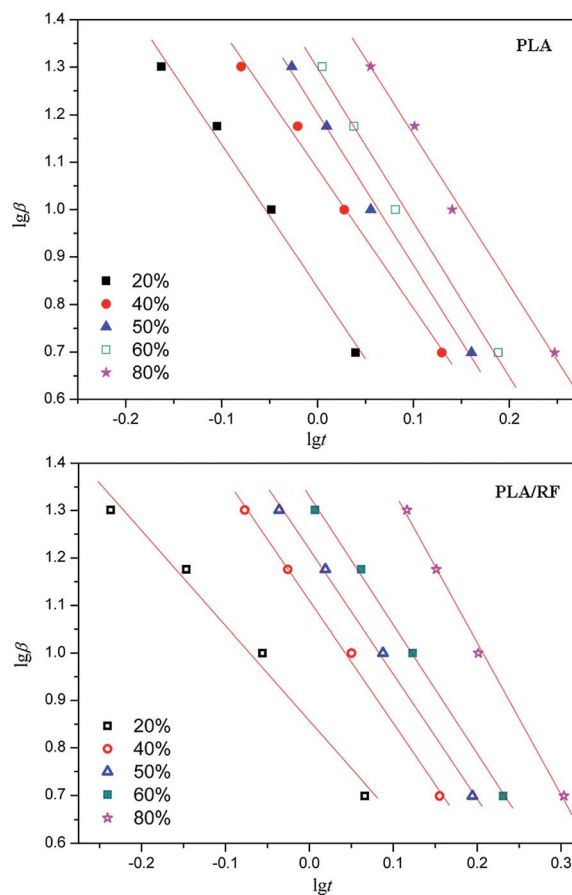

Fig. 6 The $\lg \beta$ vs. $\lg t$ linear fitting diagram for PLA and PLA/RF biocomposites.

Ozawa²⁴ proposed another analytical model to describe the crystallization behavior, as eqn (4):

$$1 - x = \exp\left(\frac{-P(T)}{\beta^m}\right) \quad (4)$$

On taking logarithm of both sides of the eqn (4), we get eqn (5):

$$\lg[-\ln(1-x)] = \lg P(T) - m \lg \beta \quad (5)$$

here, $P(T)$ is the crystallization rate constant, and m is the Ozawa index.

Fig. 4 demonstrates the crystallized fraction percentage trends of PLA and PLA/RF biocomposites changing with temperature at different heating rates. Combined with eqn (5), the relative crystallinity of PLA at four temperature points was selected to make the $\lg[-\ln(1-x)]$ vs. $\lg \beta$ diagram, as shown in Fig. 5. Clearly, the linear fit of the Ozawa model is terrible, which is reported by others²⁵ as well, meaning that the Ozawa model is not accurate in the analysis of non-isothermal crystallization behavior of PLA. This is because the Ozawa model simplifies the crystallization behavior in the material system and ignores the existence of spherulitic collision and secondary

crystallization, leading to the diagram of $\lg[-\ln(1-x)]$ vs. $\lg \beta$ that deviates from the linear relationship.^{26,27}

It has been found that the study of non-isothermal crystallization behavior will be more accurate when the Avrami equation is introduced into the Ozawa model, thus we can get a new eqn (6):

$$\lg \beta = \lg F(T) - \alpha \lg t \quad (6)$$

here, $\alpha (=n/m)$ is the ratio of Avrami index (n) and Ozawa index (m); $F(T) = [P(T)/Z]^{1/m}$, and its value is inversely proportional to the rate of crystallization.

Table 2 The crystallization kinetics parameters of the PLA and PLA/ramie at different relative crystallinity

Sample	Relative crystallinity					
	20%	40%	50%	60%	80%	
PLA	$F(T)$	6.85	12.18	15.96	19.86	29.94
	α	3.01	2.94	3.21	3.25	3.17
PLA/RF	$F(T)$	7.20	12.89	16.52	21.41	46.00
	α	2.50	2.78	3.13	2.91	3.21

Fig. 6 shows $\lg \beta$ vs. $\lg t$ linear fitting relationship for PLA and PLA/RF biocomposites. Compared with Fig. 5, the fitting degree in Fig. 6 is obviously better, and the calculated kinetic parameters are more accurate. Therefore, the combination model of Ozawa equation and Avrami equation can support the crystallization behavior research of PLA and PLA/RF biocomposites. We converted the slope and intercept of the straight line in Fig. 6 into the kinetic parameters $F(T)$ and α , and summarized the values in Table 2. It can be seen that, with the relative crystallinity changing from 20% to 80%, the crystallization rate of the material decreases, and the $F(T)$ and α values of PLA and PLA/RF are relatively close, indicating that the addition of RF has not changed the crystallization mechanism of PLA material, which is consistent with the analysis of the abovementioned Jeziorny model.

3.3. The crystallization activation energy calculation of PLA and PLA/RF biocomposites

The crystallization process of the polymer is a complex reaction process; generally, the apparent activation energy is used to describe the overall characteristics of polymers in crystallization process, and its most commonly utilized formula is the Kissinger equation:²⁸

Table 3 The apparent activation energy of PLA and PLA/RF biocomposites

Sample	Slope	Apparent activation energy (kJ mol ⁻¹)
PLA	-12.7815	106.265
PLA/RF	-10.1179	84.120

$$\ln \frac{\beta}{T_p^2} = -\frac{E_g}{RT_p} + \text{constant} \quad (7)$$

here, T_p is the temperature corresponding to the exothermic peak, E_g is crystallization activation energy, and R is the gas constant, whose value is 8.314 J mol⁻¹ K⁻¹.

According to the Kissinger equation, combining the data of thermal analysis, we obtained the $\ln(\beta/T_p^2)$ vs. $1000/T_p^2$ relationship of PLA and PLA/RF biocomposites, as shown in Fig. 7. Table 3 shows the data that convert the line fitting to apparent activation energy. We can observe that the addition of RF reduces the apparent crystallization activation energy in the process of PLA crystallization from 106.265 kJ mol⁻¹ to 84.120 kJ mol⁻¹, which indicates that the RF can reduce the energy barrier in the PLA crystallization process and be

Fig. 7 The $\ln(\beta/T_p^2)$ vs. $1000/T_p$ diagram for PLA and PLA/RF biocomposites.

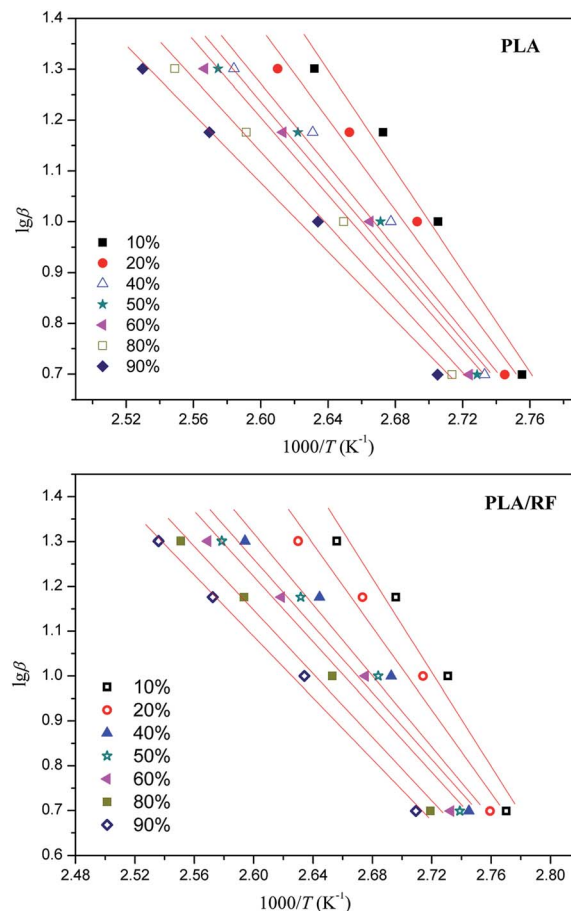

Fig. 8 The $\ln \beta$ vs. $1/T$ diagram for PLA and PLA/RF biocomposites at different relative crystallinity degrees.

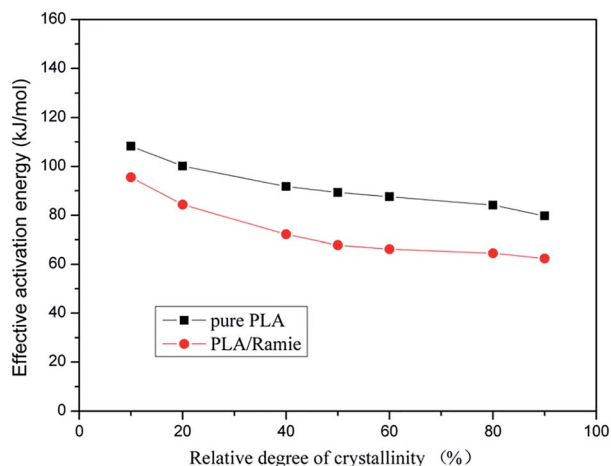

Fig. 9 Comparison of the local activation energy of PLA and PLA/RF biocomposites at different relative crystallinity degrees.

conductive to crystallization. This is consistent with the results obtained in Fig. 1, the RF, acting as polymer nucleating agent, advances the crystallization initiation time.²⁹

However, the apparent activation energy cannot express the crystallization behavior of a certain step in the crystallization process; hence, the Doyle–Ozawa model^{30,31} is usually used to calculate the local activation energy, as shown in expression (8):

$$\lg \beta = -2.315 - 0.4567E(x)(RT)^{-1} + \lg AE(x)[Rf(x)]^{-1} \quad (8)$$

here, A is a frequent constant, and $f(x)$ is called mechanism function. This method is model-independent, and hence $f(x)$ here is not an assumption, and it simplifies the computational model.

According to the Doyle–Ozawa model, a plot of $\ln \beta$ vs. $1/T$ was obtained regarding a given relative crystallinity calculated from PLA and PLA/RF thermal analysis data (as shown in Fig. 8). Moreover, the slope of each line fitting was converted into local activation energy and is summarized in Fig. 9.

Fig. 9 shows that the local activation energy of PLA and PLA/RF is consistent with the variation in crystallinity, and the former has a slowdown trend with the increase of relative crystallinity. The average local activation energy of PLA and PLA/RF is $91.562 \text{ kJ mol}^{-1}$ and $73.292 \text{ kJ mol}^{-1}$, respectively, which is in accordance with the calculated results of apparent activation energy, indicating that the addition of RF could reduce the energy barrier in the crystallization process of PLA.

4. Conclusions

Poly(lactic acid)/ramie fiber laminated biocomposite based on the non-woven RF and PLA short fibers has been successfully prepared through hot-press molding. Differential scanning calorimetry was used to study the non-isothermal crystallization kinetics of pure PLA and PLA/RF biocomposites with 40 wt% ramie fiber. The results determined that the addition of the RF could propel the crystallization process of PLA, during which the RF played a role in heterogeneous nucleation. Furthermore,

Jeziorny, Avrami, Ozawa, Kissinger and other models were used to investigate the crystallization mechanism and crystallization kinetics parameters of PLA and PLA/RF biocomposites, respectively. The Jeziorny model indicated that the crystallization process of PLA and PLA/RF biocomposites could be divided into two stages. Moreover, the Jeziorny and Ozawa–Avrami models both confirmed that the addition of RF did not change the crystallization mechanism of PLA compared with that of pure PLA. In addition, the Doyle–Ozawa model's results revealed that the addition of RF weakened the interaction between PLA chains and reduced the energy barrier of PLA in the crystallization process for the ramie fiber-reinforced PLA materials, which could benefit the comprehensive performance of the PLA/RF biocomposite.
