The effect of doping graphene oxide on the structure and property of polyimide-based graphite fibre†

Meng Xiao,^a Na Li,^a Zhaokun Ma,^{a*} Huaihe Song,^a Kang Lu,^a Ang Li,^a Yuchen Meng,^a Dingling Wang^a and Xi Yan^b

Herein, graphite fibres were prepared from polyimide (PI) fibres by doping varying contents of graphene oxide (GO) into polyimide (PI) fibres through a carbonization and graphitization process. By *in situ* polymerization, GO/polyamic acid (PAA) was synthesized and used for preparing GO/PI fibres *via* dry-jet wet spinning. During the spinning process, the molecular orientation of GO/PI fibres was forced to follow the fibre axis under the strong shear force at the spinneret. The DSC results show that the exothermic intensity of 1.0 wt% GO/PI composite fibres declined by 69.7% than that of the pure PI fibre; this prevented the breakage of PI molecular chains and maintained the preferred orientation of the GO/PI fibres. During the graphitization process, GO sheets were reduced to grain graphene, acting as nucleus crystals, which could enlarge the size of microcrystals of graphite and increase the degree of graphitization. PI fibres as a carbon precursor showed great potential in the preparation of graphite fibres with high thermal conductivity, and GO doping can improve the thermal conductivity of the composite graphite fibres. When 2.0 wt% GO was added, the thermal conductivity of the GO/PI composite graphite fibre could reach 435 W m⁻¹ K⁻¹, which was twice that of the pure PI-based graphite fibre.

Introduction

With the increasing energy density of electronic devices, electronic devices are generating a large amount of heat when in use. If the heat does not conduct to the environment immediately, the temperature of electronic devices will increase, and this may even cause security issues. To conduct heat quickly, we need high thermal conductivity materials (TCMs). Metals have been used as traditional TCMs due to their high thermal conductivity; however, since they are heavy, inflexible, and have relatively high thermal expansion coefficients, they are not ideal for cooling silicon-based electronic devices.¹ Carbon materials,

due to their unique electron structures that have both sp² and sp³ hybrid orbitals and unique phonon heat conduction mechanism, are very likely to produce high TCMs.²

Among various carbon precursors, aromatic polyimide (PI) with different chemical structures can be easily graphitized at a relatively high temperature above 2200 °C and changed into a highly crystalline graphite structure.^{3,4} Graphite films derived from PMDA-ODA-type PI films can obtain an ultrahigh thermal conductivity of 1700 W m⁻¹ K⁻¹ in the plane direction.⁵ Many researchers have studied the influence of chemical structure,^{6,7} drawing ratio,^{8,9} and heat-treating¹⁰ conditions on the performance of graphite films. Various identification methods^{11,12} have been used to illustrate the mechanism of pyrolysis strategy of polyimide films, and the behaviour of polyimide films has also been examined.^{6,13-15}

PI fibres are a class of high performance polymer fibres, which are used mainly in heat resistance areas such as high temperature dust removal and flame-retardant protective clothing. Researchers have found that PI fibres can be transformed into graphite fibres with thermal conductivity higher than that of PAN-based carbon fibres through simple heat treatment.^{16,17} Li Ang *et al.* found that both the degree of graphitization and thermal conductivity of PI-based graphite fibres were improved with an increase in the heat treating temperature.^{18,19} Zhang *et al.* studied the structure evolution of polyimide fibres with different chemical structures during the carbonization process and discovered that the carbon yield and graphitization degree depended strongly on the chemical structure of the PI fibre.²⁰

Graphene (GO)/polymer composites have been widely studied due to their excellent properties and high solubility of GO.^{21,22} Graphite oxide (GO)²³ consists of a two-dimensional graphene sheets with a number of oxygen functional groups, such as hydroxyl, epoxide, and carbonyl groups, at its edges and basal planes.^{23–25} Substituted with oxygen functional groups, GO dissolved well in water and other polar solvents such as DMF, DMAc *etc.* *Via in situ* polymerization, GO sheets can combine with the polymer chains due to van der Waals forces.²⁶ When the polymer chains attach to the large planer sheets of GO, the orientation of the composite material can be improved by optimizing the orientation of GO sheets.^{1,24,27} Ting Huang *et al.* conducted detailed investigations to illustrate that an optimized orientation of GO in the composite material could enhance the performance and increase the thermal stability of the composite materials.²⁸ Chen min-gua²⁹ found that the mechanical property, thermal conductivity, and electric conductivity clearly increased with the addition of a small amount of GO. Dong *et al.*³⁰ prepared GO/PI composite fibres with ODA-modified GO and found that the incorporation of graphene greatly improved the thermal stability and hydrophobic behaviour of the composite fibre. Wang *et al.*²⁴ fabricated GO/PI composite films *via in situ* polymerization and found that the Young's modulus of the GO/PI composite films was 15 times greater and the tensile strength was 9 times greater than those of the pure PI films.

Herein, we prepared graphite fibres by doping different contents of GO in polyimide. Doping of GO improved the orientation of the GO/PI composite fibre during the spinning process. The TG-DSC curves indicate that addition of GO can increase the thermal stability and reduce exothermic intensity during carbonization such that the preferred molecular orientation of carbon fibres can be maintained. GO sheets acted as crystals during the carbonization and graphitization process and increased the degree of graphitization of the PI/GO-based graphite fibre. After graphitization at 2800 °C, the mechanical property and thermal conductivity improved. When 2.0 wt% GO was added, the thermal conductivity of the GO/PI composite graphite fibres could reach 435 W m⁻¹ K⁻¹, which was twice that of the pure PI-based graphite fibre.

Experimental

Materials

Natural graphite was purchased from Qingdao Graphite Co., Ltd. Pyromellitic dianhydride (PMDA) and 4,4-oxydianiline (4,4-ODA) were purchased from Sinopharm Chemical Reagent Co., Ltd. and sublimated under vacuum at 110 °C for 5 h. *N,N*-Dimethylacetamide (DMAc) was purchased from Tianjin Guangfu fine chemical Research Institute.

Preparation of the graphene oxide/polyamic acid (GO/PAA) solution

As shown in Scheme 1, GO was prepared *via* the modified Hummers method and then dispersed in *N,N*-dimethylacetamide (DMAc) *via* ultrasonic dispersion. The GO/PAA solution

Scheme 1 Schematic for the preparation of PMDA/ODA type polyimide.

was synthesized by dissolving 4,4-oxydianiline (4,4-ODA) in GO dispersion and then adding an equimolar amount of pyromellitic dianhydride (PMDA) gradually. The solution was then stirred at 0 °C for 2 h under the atmosphere of pure nitrogen, having a concentration of 15 wt% in DMAc. The GO/PAA solution, as shown in Fig. 2(a), was degassed at a low temperature to remove the gas in the solution and obtain a homogeneous solution.

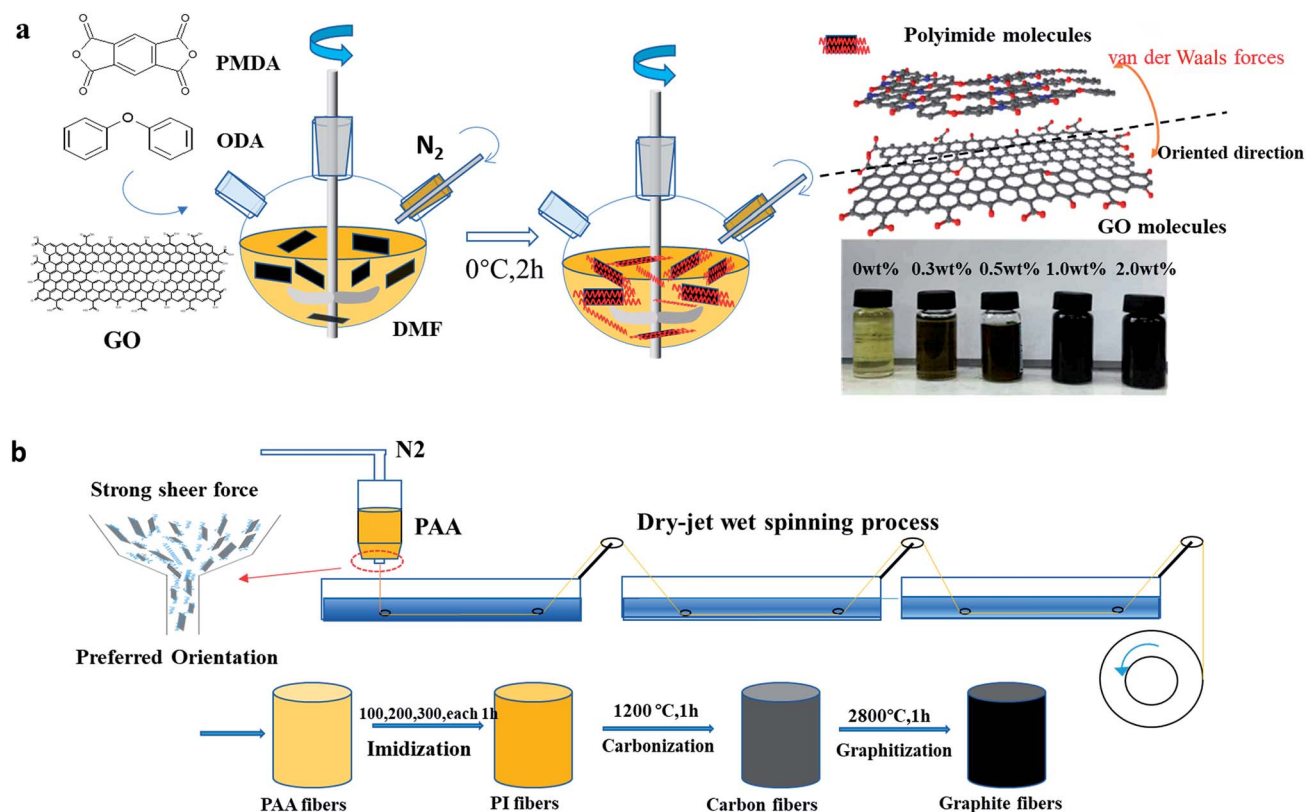

Preparation of the graphite oxide/polyimide (GO/PI) composite fibre

As shown in Scheme 2(a), the GO/PAA fibres were fabricated by extruding the GO/PAA solution through the spinneret (single hole, 0.2 mm in diameter) using high-pressure nitrogen into a coagulation bath of 10% ethanol water. The temperature of the coagulation bath is in the range from 25 °C to 40 °C. The GO/PAA fibres were obtained through a spinning roller. The pressure of nitrogen and the speed of the roller were controlled to decrease the diameter of the GO/PAA fibres. The GO/PAA fibres were tensioned and put in a vacuum environment to remove the solvent in the fibres. The GO/PI fibres were obtained by heating the GO/PAA fibres at 100 °C, 200 °C, and 300 °C, with each stage holding for one hour at a heating rate of 5 °C per minute.^{31,32}

Carbonization and graphitization of the GO/PI composite fibre

The prepared GO/PI fibres were put into corundum crucibles and covered by a graphite sheet to reduce the shrinkage of the fibre. As shown in Scheme 2(b), the GO/PI fibres were carbonized at 1200 °C in high-purity nitrogen for 1 hour at a heating rate for 5 °C per minute. Then, the GO/PI-based carbon fibres were graphitized at 2800 °C in high-purity argon for 1 hour at a heating rate of 10 °C per minute to obtain GO/PI-based graphite fibres.

Scheme 2 (a) Preparation of the GO/PAA solutions and (b) preparation of the GO/PI-based graphite fibres.

Characterization

Fourier transform infrared (FTIR) spectroscopy

Fourier transform infrared spectroscopy (FTIR, Thermo Nicolet IS50 Series) was used to investigate the molecular structure and chemical bonding groups of the GO/PI composite fibres with attenuated total reflectance in the range from 4000 to 650 cm^{-1} .

Scanning electron microscopy (SEM)

An SEM (Zeiss Supra 55) operating at 20 kV was used to observe the surface and cross-section morphologies of the GO/PI-based graphite fibre. The graphite fibres were aligned along the same direction and embedded in epoxy resin. Then, the samples were put in liquid nitrogen and quickly broken into two pieces to investigate the morphology of the cross-section. All the samples were treated by gold-spray before observation.

Thermal gravimetric analysis (TG)/differential scanning calorimetry (DSC)

The Thermal Sync Analyzer (NETZSCH STA 499C, German) was used to investigate the thermal stability of the GO/PAA fibres and GO/PI fibres. The TG/DSC curves were obtained by heating the samples from room temperature to 1000 $^{\circ}\text{C}$ under a high-purity argon atmosphere at a heating rate of 5 $^{\circ}\text{C}$ per minute. The calibrated baseline was obtained before sample measurement, and the samples were tested under the same conditions.

X-ray diffraction (XRD)

The crystalline structure of the graphite fibre was examined by X-ray diffraction (XRD) using a diffractometer (X'Pert Pro, Analytical Co., Ltd). The diffracted intensity of Cu $K\alpha$ radiation (λ 0.1542 nm; 40 kV and 40 mA) was measured between 5 and 90 $^{\circ}$. We used 2θ to represent the position of the (002) diffraction peak.

According to the Bragg's equation, we can obtain the average interlayer spacing of d_{002} .

$$\lambda = 2d \sin \theta \quad (1)$$

According to the Scherrer formula, the average size of the crystallite L_a and the average crystallite thickness L_c can be calculate as follows:

$$L_a = \frac{0.89\lambda}{B \cos \theta} \quad (2)$$

$$L_c = \frac{0.45\lambda}{B \sin \theta} \quad (3)$$

B represents the full wave at half maximum (FWHM) of the d_{002} peak.

According to the Mering-Maire empirical formula, the graphitization degree of graphite fibres can be calculated as follows:

$$G = \frac{0.344 - d_{002}}{0.344 - 0.3354} \times 100\% \quad (4)$$

Herein, the average interlayer spacing of the ideal graphite crystal is 0.3354 nm, and the average interlayer spacing of amorphous carbon is 0.344 nm.

Raman

A laser Raman spectrometer (LabRam HR800, Horiba Jobin Yvon Inc.) was used to investigate the structure of GO/PI-based graphite fibres in the scanning range of 0–4000 cm^{-1} . The degree of graphitization can be represented by the value R , which is calculated by the formula $R = I_D/I_G$. The smaller the R value, the higher the degree of graphitization.

Mechanical property of the graphite fibre

The mechanical property data of the composite carbon fibres was obtained by the single fibre testing method (YG001A, Taicang Instrument Corp. of China) according to the ASTM standard D3544-76 procedure. The average tensile strength and elongation at break were obtained by testing 50 single filaments for each set.

Thermal conductivity of the graphite fibre

The Shangtai EC430 resistivity meter was used to measure the electrical resistivity of the composite carbon fibre; for each sample, it was measured 30 times to obtain an average value. In our study, the thermal conductivity of GO/PI-based graphite fibres was calculated according to the following empirical formula:³³

$$\lambda = 1261/\rho \quad (5)$$

herein, λ is the thermal conductivity ($\text{W m}^{-1} \text{K}^{-1}$) of GFs, and ρ is the electrical conductivity ($\mu\Omega \text{m}^{-1}$) of GFs.

Results and discussion

Chemical structure and morphology of the PI fibres and GO/PI composite fibres

As shown in Fig. 1, the two-adjacent peaks around 1718 cm^{-1} and 1776 cm^{-1} demonstrate the formation of an imide group and the five-membered cyclic structure of polyimide, accompanied by the disappearance of amide groups at 1550 cm^{-1} . The sharp peak at 1373 cm^{-1} represents the stretching vibration peak of the C–N bond, and the sharp peak at 721 cm^{-1} represents the bending vibration of the C=O bond, which together indicate the formation of polyimide. The sharp peak at 1250 cm^{-1} shows the existence of an ether group in the molecular chains.

With an increase in the GO content in the composite fibre, the intensity of the stretching vibration peak of OH group increased. The smaller peak at 1250 cm^{-1} represents the stretching vibration peak of the C–O–C bond, which indicates excellent flexibility of the molecular chains. The peak at 1715 cm^{-1} represents the C–C=O bond, and the peak at 1500 cm^{-1} represents benzene. An increase in the intensity ratio of benzene bond and C–C=O bond indicates the reaction of GO and PI molecular chains. It can be inferred that the PI molecular

Fig. 1 FTIR spectrum of the pure PI and GO/PI fibres with different GO contents.

chains are fixed on the surface of the GO sheet due to π – π conjugation. The orientation of the GO sheet can be controlled to be along the fibre axis during the spinning process. Moreover, the orientation of the PI molecular chains can be induced to be along the fibre axis.

Fig. 2 shows the surface and cross-sectional morphology of GO/PI-based graphite fibres with different GO contents. As shown in the images (A and B), the surface of pure PI is quite smooth, and the cross-section images show that it has several holes on it; this indicates the brittle fracture of the pure PI-based graphite fibres. The images C and D show the surface and cross-sectional morphology of the 0.3 wt% GO/PI-based graphite fibre. The magnified parts of the image C show several grooves on the surface of the fibre along the fibre axis; this indicates that addition of GO can improve the orientation of the graphite fibre. From image D, it is clear that the surface of the 0.3 wt% GO/PI-based graphite fibre is rough; thus, the mechanical quality of the composite fibre is high. For the 2.0 wt% GO/PI composite graphite fibres, the grooves on its surface become wider, and cross-sectional parts become rougher.

Thermal stability of the PI fibre and GO/PI composite fibre

TG-DSC analysis was carried out under nitrogen for investigating the thermal stability of the PAA fibres and GO/PAA fibres. From room temperature to 150 $^{\circ}\text{C}$, both the PAA fibres and GO/PAA fibres experienced a 5% weight loss, which was probably because of solvent evaporation inside the fibres. From 150 $^{\circ}\text{C}$ to 220 $^{\circ}\text{C}$, both the PAA fibres and GO/PAA fibres experienced an obvious weight loss of about 20–30%, which indicates that the PAA fibres change into aromatic PI fibres. Then, the PI fibres experienced about 30% weight loss above 500 $^{\circ}\text{C}$, which indicates that the aromatic structure turns into amorphous carbon. From 150 $^{\circ}\text{C}$ to 700 $^{\circ}\text{C}$, the residual weight of the GO/PAA fibres is higher than that of the PAA fibres; this indicates that doping

Fig. 2 Surface and cross-sectional morphology of the graphite fibres based on (A and B) pure PI, (C and D) 0.3 wt% GO/PI, (E and F) 2.0 wt% GO/PI.

of GO improves the thermal stability of the GO/PAA fibres. However, the residual weight of the GO/PAA fibre was lower than that of the PAA fibres above 700 °C; this was mainly because doping of GO increased the decomposition rate of the GO/PAA fibres.

PI fibres are a kind of high-temperature resistant polymer fibres, which are mainly used in a flame retardant area. The TG-DSC analysis of the PI fibres and GO/PI fibres was carried out in air. Fig. 3 demonstrates the thermal stability of the pure PI fibres and GO/PI composite fibres with different GO contents. As shown in Fig. 3, the 10% weight loss temperature of the GO/PI composite fibre with 1.0 wt% GO is 509 °C, which is nearly 40 °C higher than that of the pure PI fibre. From Fig. 3, we can observe that the initial decomposition temperature of the GO/PI

composite fibre is higher than that of the pure PI fibres; this indicates that GO doping can increase the thermal stability of the GO/PI fibres. Fig. 4 shows the DSC curves of the PI fibres and GO/PI composite fibres.

From Fig. 4, it can be clearly observed that the GO/PI composite fibre with 1 wt% GO has a exothermic peak temperature and lower exothermic peak intensity than that of the pure PI fibre. The exothermic peak temperature of the GO/PI composite fibre with 1 wt% GO added increases by 7% than that of the pure PI fibre, and the exothermic intensity drops by 69.7%. It can be inferred that the addition of GO can effectively increase the thermal stability and decrease the exothermic heat of GO/PI fibres during the carbonization process. The reason

Fig. 3 TG curves of the pure PI fibres and GO/PI composite fibres.

Fig. 4 DSC curves of the pure PI fibres and GO/PI composite fibres.

why doping of GO can improve the thermal stability and decrease the exothermic heat can be inferred for the following two reasons. First, GO sheets have a strong interaction with PI molecular chains and may form a crosslinking structure, which greatly decreases the heat released during carbonization. Second, GO sheets can hinder the movement of the PI molecular chains; this increases the energy needed to break the PI molecular chains.

Crystalline structure of PI-based graphite fibres and GO/PI composite graphite fibres

Fig. 5 displays the diffraction patterns of the GO/PI-based graphite fibres with different GO contents. The diffraction peak around 26° indicates the development of (002) planes. The existence of the (004) peak indicates the formation of a graphite structure. With the increase of the GO content, the diffraction angle of (002) moved to a higher degree; this indicated the decrease of d_{002} , revealing that doping of GO could induce crystallization. The value of d_{002} of the graphite fibre with 2.0 wt% GO is 0.3392 nm, which is very close to that of the ideal graphite crystal (0.3354 nm). As shown in Table 1, both the average crystallite size L_a and the average crystallite thickness L_c were increased with the increase of the GO content; this indicated that doping of GO could induce the growth of graphite crystallite.

It can be inferred that GO with a large surface area acts as a crystal nucleus, which can induce the crystallization of graphite fibres. As abovementioned, the PI molecular chains were attached to the graphene sheets and then graphitized to the graphene net during the graphitization process. As the process of graphitization carries on, the layer of graphene sheets grows; this indicates the formation of graphite crystallites. The degree of graphitization increased as the GO content raised; this proved our speculation. The increase of graphitization could be confirmed by Raman spectroscopy.

Table 1 The result of XRD analysis of the GO/PI-based graphite fibres^a

Sample	2θ ($^\circ$)	d_{002} (nm)	L_a (nm)	L_c (nm)	G (%)
PI	25.83	0.3449	5.73	12.63	—
0.3 wt% GO/PI	25.92	0.3437	5.99	13.18	3.5
0.5 wt% GO/PI	25.93	0.3436	6.72	14.77	4.6
1.0 wt% GO/PI	26.16	0.3407	10.62	23.10	38.4
2.0 wt% GO/PI	26.27	0.3392	13.47	29.19	55.8

^a L_a represents the average size of crystallite, and L_c stands for the average crystallite thickness.

Laser Raman spectrum was used to examine the crystallite structure of the graphite fibre with different GO contents. For carbon materials, the D band is caused by the defects and disorder, whereas the G band is caused by the stretching of all sp^2 bonding atoms. For the graphite material, the value of $R = I_D/I_G$ is positive, related to the size of graphite crystallites, which can be used to represent the degree of graphitization. The lower the value of R , the higher the degree of graphitization. During the graphitization process, GO as a crystal nucleus could induce the formation of graphite crystallites. As shown in Fig. 6, the value of R increased with the addition of GO; this indicated the increase of the graphitization degree (Table 2).

Fig. 7 displays the orientation curves of the GO/PI-based carbon fibres and graphite fibres were obtained using XRD. Both the value of π and the value of ϕ indicate the orientation degree of the graphite fibre. With an increase in the heat treatment temperature from 1000°C to 2800°C , the value of π increases by 23.3%; this indicates that high temperature treatment can improve the orientation of the graphite fibre. The orientation degree of the GO/PI-based graphite fibre with 0.3 wt% GO added is higher than that of the pure PI fibre; this indicates that GO can promote fibre orientation.

The orientation of the GO/PI-based graphite fibres was examined by XRD. A bunch of aligned graphite fibres were fixed

Fig. 5 XRD curves of the GO/PI-based graphite fibres with different GO contents.

Fig. 6 Raman spectrum of GO/PI-based graphite fibres with different GO contents.

Table 2 The result of orientation curves analysis of the GO/PI-based graphite fibres

Sample	HTT/°C	FWHM	$\pi/^\circ$	ϕ
PI	1000	64.30	64.28	57.85
	2800	41.96	76.69	69.02
0.3 wt% GO/PI	1000	52.21	70.99	63.90
	2800	33.51	81.38	73.25

**Fig. 7** The orientation curves of the GO/PI-based graphite fibers.

to the sample cell at both ends, with the fibre length less than 5 mm. The samples were placed perpendicular to the X-ray, and the counter tube is placed at the maximum intensity of the (002) diffraction peak. Upon rotating the sample station in all directions, the reflected intensity was determined to obtain the diffraction pattern with the highest intensity of the meridian. The orientation degree π can be calculated according to the value of the full width at half maximum (FWHM):

$$\pi = \frac{180 - H}{180} \times 100\% = \frac{180 - 2Z}{180} \times 100\% \quad (H = 2 \times Z) \quad (6)$$

Herein, H represents the value of FWHM, and Z represents the orientation angle.

For the graphite fibre, a certain angle between the normal direction of the microcrystalline plane and the fibre orientation axis is called ϕ . The angle ϕ is used to characterize the degree of orientation. The higher the value of this angle, the better the orientation.

$$\phi = 90 - Z \quad (7)$$

As abovementioned, GO can promote the orientation of the as-spun PAA fibres. The PI molecular chains were attached to the GO sheets according to the π - π interaction. The orientation of GO sheets was forced to be along the fibre axis due to the strong shear force during the spinning process; this allowed the PI molecular chains to form along the fibre axis at the same time. During the carbonization and graphitization process, GO

acts as a crystal nucleus and can induce the proper arrangement of graphite microcrystals, thus improving the orientation of the graphite fibre.

Mechanical property and thermal conductivity of the graphite fibre

Fig. 8 shows the tensile strength and breaking elongation of GO/PI-based graphite fibres with different GO contents. From Fig. 8, it is clear that the breaking elongation decreases with the addition of GO, and the tensile strength decreases beyond that at 0.3 wt% with the addition of GO. The tensile strength of 0.3 wt% GO-added graphite fibre is 693.89 MPa, which increases by 67.7% as compared to that of the pure PI-based graphite fibre, whereas the tensile strength of 0.5 wt% GO decreases by 37.2% as compared to that of 0.3 wt% GO. It can be inferred that the mechanical quality of the GO/PI composite graphite fibre can be improved by adding a certain amount of GO. If too much GO is added, the mechanical properties of graphite fibre will decrease since GO cannot disperse well in the fibre. The over added GO will aggregate in the fibre and form defects, which can limit the property of the fibre. Moreover, with an increase in the GO content, the breaking elongation of the graphite fibre decreases; this indicates the increase of tensile modulus of graphite fibre. Due to the improvement of fibre orientation, the mechanical properties of the composite graphite fibre was improved as well.

The electrical resistance and thermal conductivity of the mesophase carbon fibre has an empirical equation, which is $\lambda = 1261/\rho$ (λ represents the thermal conductivity, and ρ represents the electric resistivity). A resistivity meter was used to measure the electrical resistance, and then, the thermal conductivity was calculated according to the equation. As shown in Fig. 9, the thermal conductivity increased with the addition of GO. The thermal conductivity of the GO/PI-based graphite fibre with 2.0 wt% GO content is 435.5 W m⁻¹ K⁻¹ and is 81.2% higher than that of the pure PI-based graphite fibre. The increased thermal conductivity of the composite graphite fibre may due to two reasons: the first reason is that the orientation along the

**Fig. 8** Tensile strength and breaking elongation of the GO/PI-based graphite fibres with different GO contents.

Fig. 9 The thermal conductivity of GO/PI-based graphite fibre with different GO contents.

fibre axis is improved during the spinning process and the beginning of carbonization process, another reason is that GO addition has induced the crystallization of the graphite fibre. Still, we need to find a balance between good mechanical property and high thermal conductivity. It can be reasonably believed that PI fibres are an ideal carbon precursor to prepare graphite fibre with high thermal conductivity.

Conclusions

The influences of addition of GO on the structure and properties of a GO/PI-based graphite fibre were carefully studied. In our study, we prepared graphite fibres with different GO contents and used different methods, such as FTIR spectroscopy, TG-DSC, XRD, and Raman spectroscopy, to characterize graphite fibres. Through a series of identification tests, it was found that the addition of GO can improve the orientation along the fibre axis and increase the degree of graphitization; thus, we can obtain a graphite fibre with a high mechanical property and high thermal conductivity. According to the TG-DSC curves, a GO/PI-based graphite fibre with 1 wt% GO addition has a 7% higher exothermic peak temperature and 69.7% lower exothermic peak intensity than the pure PI fibre; this indicates that doping of GO can improve the thermal stability and therefore maintain the preferred orientation of the graphite fibre. XRD and Raman curves indicate that doping of GO can increase the degree of graphitization of the graphite fibre because GO sheets act as a nucleus crystal during the graphitization process. GO can improve the orientation of the GO/PI composite fibres during the spinning process and maintain the preferred orientation during the beginning process of carbonization; thus, we can fabricate a graphite fibre with higher mechanical properties and thermal conductivity. Although the increase of graphitization degree can increase the thermal conductivity of the graphite fibre, it will decrease the mechanical properties of the graphite fibre. It is better to have a balance between mechanical properties and thermal conductivity, and we found that 0.3 wt% addition amount of GO is a better choice. In this study, we introduced a new approach

to prepare graphite fibres with high thermal conductivity from PI fibres, and these fibres have potential application in heat management areas.
