# Construction of C<sub>60</sub>-decorated SWCNTs (C<sub>60</sub>-CNTs)/bismuth-based oxide ternary heterostructures with enhanced photocatalytic activity†

Xue Lin, Yang Xi, Rui Zhao, Junyou Shi \* and Ning Yan\*

Novel nanostructured carbon/BiVO<sub>4</sub> and nanostructured carbon/Bi<sub>2</sub>MoO<sub>6</sub> nanocomposite photocatalysts were fabricated via a facile hydrothermal process by using fullerene (C<sub>60</sub>)-decorated single-walled carbon nanotubes (SWCNTs) as the carbon source, which are denoted as C<sub>60</sub>-CNTs. The fabricated nanocomposites were characterized by various analytical techniques. The results showed that the C<sub>60</sub>-CNTs are intimately bound to the bismuth-based oxide surfaces. The UV-vis diffuse reflectance spectra of C<sub>60</sub>-CNTs/bismuth-based oxide nanocomposites exhibited increased visible-light absorption compared to pure bismuth-based oxides. Moreover, the ternary nanocomposites demonstrated significantly enhanced photocatalytic activity for the degradation of rhodamine B (Rh B) under visible light. The enhanced performance is attributed to the extended absorption in the visible-light region resulting from the incorporation of C<sub>60</sub>-CNTs, high specific surface area, and efficient separation of electron-hole pairs by the ternary composite system. In addition, the radical-trapping experiments revealed that the holes and O<sub>2</sub><sup>•-</sup> play major roles in the decolorization of Rh B under visible-light irradiation.

## 1. Introduction

Semiconductor photocatalysis is a promising environmental remediation technology that can be used to treat inorganic or organic pollutants in the environment.<sup>1–3</sup> To date, many semiconductor photocatalysts have been studied for use in water splitting and/or environmental remediation.<sup>4–6</sup> Among them, bismuth-based semiconductors (*e.g.*, Bi<sub>2</sub>WO<sub>6</sub>, BiVO<sub>4</sub>, Bi<sub>4</sub>Ti<sub>3</sub>O<sub>12</sub>, Bi<sub>2</sub>O<sub>2</sub>CO<sub>3</sub>, BiOI and Bi<sub>2</sub>MoO<sub>6</sub>) have attracted great attention due to their many advantages, such as superior photocatalytic performance under UV and visible light irradiation, unique layered structures, resistance to photocorrosion, chemical stability, low/non-toxicity, and abundance in the earth.<sup>7–12</sup> Among the various bismuth-based semiconductors, BiVO<sub>4</sub> with a band gap of around 2.40 eV is a strong candidate because of its properties that include good photoconductivity and significant visible-light response.<sup>13,14</sup> However, some researches have revealed that the photocatalytic activity of pure BiVO<sub>4</sub> is comparatively low due to the difficulty in the separation of photogenerated electron-hole pairs.<sup>14</sup> Bi<sub>2</sub>MoO<sub>6</sub>, with excellent intrinsic physical and chemical properties, exhibits photocatalytic activity for water splitting and organic pollutant

degradation.<sup>15,16</sup> Nevertheless, pure Bi<sub>2</sub>MoO<sub>6</sub> itself has been a bit of a disappointment as a photocatalyst due to the fast recombination of the photo-induced electrons and holes in the material. Much work is centered on methods that can transform BiVO<sub>4</sub> or Bi<sub>2</sub>MoO<sub>6</sub> into a more efficient visible light photocatalytic material.<sup>17–19</sup> Among the various methods, the construction of composite photocatalysts has shown to be an effective approach for improving the photocatalytic efficiency for the degradation of organic contaminants.<sup>19</sup>

In recent years, carbonaceous materials such as activated carbon (AC), carbon dots (CDots), fullerene (C<sub>60</sub>), carbon nanotubes (CNTs) and graphene have been widely employed for the enhancement of photocatalytic performances of semiconductors, which has thus attracted considerable attention.<sup>19,20</sup> Carbon nanostructured materials have been used as coupling materials for bismuth-based composites due to their excellent electron accepting and electron-transporting properties.<sup>20</sup> Over the past few years, combination of two kinds of carbon materials such as C<sub>60</sub>-CNTs, C<sub>60</sub>-RGO, and GO-CDots as a new class of carbon nanostructured materials has attracted much attention due to their extraordinary electronic, optical, and chemical properties.<sup>21,22</sup> Moreover, there are many reports on composites containing SWCNTs and C<sub>60</sub> clusters, which are known to decorate the SWCNT sidewall through covalent or noncovalent interaction.<sup>21</sup> Although MWCNTs, SWCNTs, and C<sub>60</sub> have been widely investigated for coupling with semiconductor materials, studies on the photoactivity of the above-

† Electronic supplementary information (ESI) available. See DOI: 10.1039/c7ra11056a

mentioned novel C<sub>60</sub>-CNTs hybrid carbon materials coupled with bismuth-based oxides are still scarce, and the photocatalytic mechanism of the composite photocatalyst remains unclear.

Herein, we report two novel C<sub>60</sub>-CNTs/bismuth-based oxide composite photocatalysts fabricated through sensitizing leaf-like BiVO<sub>4</sub> and sheet-like Bi<sub>2</sub>MoO<sub>6</sub> with C<sub>60</sub>-CNTs hybrid carbon materials *via* a facile hydrothermal method for the first time. The photocatalytic performances of the composites were examined by degrading rhodamine B (Rh B) under visible-light irradiation ( $\lambda > 420$  nm). The experimental results showed that the as-prepared C<sub>60</sub>-CNTs/bismuth-based oxide composites exhibited excellent photocatalytic activity. Moreover, the possible photocatalytic mechanism of the composite materials related to the band positions of the semiconductors have also been discussed in detail.

## 2. Experimental section

### 2.1 Preparation of photocatalysts

**2.1.1 Preparation of C<sub>60</sub>-CNTs.** All reagents for synthesis and analysis were commercially available and used without further treatments. C<sub>60</sub>-CNTs hybrids were prepared by using the Zhang's method:<sup>21</sup> 50 mg of SWCNTs and 50 mg of C<sub>60</sub> were dispersed by ultrasonication in 100 mL toluene for 1 h, and then stirred at room temperature for 12 h. After volatilization of toluene, the resultant black powder was washed with ethanol for several times and dried in vacuum at 80 °C for 12 h to obtain the C<sub>60</sub>-decorated SWCNTs (50 wt% C<sub>60</sub>-CNTs, denoted as C<sub>60</sub>-CNTs).

**2.1.2 Preparation of C<sub>60</sub>-CNTs/BiVO<sub>4</sub> and C<sub>60</sub>-CNTs/Bi<sub>2</sub>MoO<sub>6</sub>.** The nanostructured carbon/bismuth-based oxide nanocomposites were prepared by a hydrothermal method. For example, in a typical synthetic process for nanostructured carbon/BiVO<sub>4</sub>, 15 mg of C<sub>60</sub>-CNTs was dispersed in 15 mL water by sonication, and Bi(NO<sub>3</sub>)<sub>3</sub>·5H<sub>2</sub>O (0.88 mmol) and NH<sub>4</sub>VO<sub>3</sub> (0.88 mmol) were added to the mixture and stirred for additional 1 h at room temperature. The theoretical weight ratio of C<sub>60</sub>-CNTs to BiVO<sub>4</sub> was 1 : 19 for the nanostructured carbon/BiVO<sub>4</sub> (2.5 wt% C<sub>60</sub>/2.5 wt% CNTs/BiVO<sub>4</sub>, denoted as C<sub>60</sub>-CNTs/BiVO<sub>4</sub>). After carefully adjusting the pH value to 3 using 25 wt% NH<sub>3</sub>·H<sub>2</sub>O solution, the resulting mixture was transferred into a 20 mL Teflon-lined stainless steel autoclave and kept at 150 °C for 24 h. The obtained product was collected by centrifugation, washed with water and ethanol several times, and then dried at 80 °C overnight. C<sub>60</sub>-CNTs/Bi<sub>2</sub>MoO<sub>6</sub> was prepared *via* a similar process.

### 2.2 Characterization of photocatalysts

X-ray diffraction (XRD) was carried out on a D/MAX 2500V diffractometer (Rigaku, Japan) with monochromatized Cu K $\alpha$  radiation,  $\lambda = 0.154$  18 nm, in the  $2\theta$  range of 10 to 70°. The morphologies and microstructures of the products were characterized by transmission electron microscopy (TEM, JEM-2100F). X-ray photoelectron spectroscopy (XPS, VGScientific) using 300 W Al K $\alpha$  radiation as the excitation source was applied

to study the composition and chemical states of the elements. The FT-IR spectra were recorded on an FTIR spectrometer (America Perkin Elmer, Spectrum One) using the standard KBr disk method. UV-vis absorption spectra of the samples were tested on a scan UV-vis spectrophotometer (Shimadzu, UV-2550) equipped with an integrating sphere using BaSO<sub>4</sub> as the reference sample. The surface areas were measured by the nitrogen adsorption Brunauer–Emmett–Teller (BET) method (BET/BJH surface area, 3H-2000PS1). The photoluminescence (PL) spectra of the photocatalysts were obtained using a F4500 (Hitachi, Japan) photoluminescence detector with an excitation wavelength of 325 nm.

### 2.3 Photocatalytic activities studies

The photocatalytic properties of the as-prepared samples were evaluated using Rh B as a model compound. In the experiments, the Rh B solution (0.01 mmol L<sup>-1</sup>, 100 mL) containing 0.02 g of photocatalyst was mixed in a pyrex reaction glass. The reactivity experiments were carried out in air at room temperature. A 300 W Xe lamp ( $\lambda > 420$  nm) with 100 mW cm<sup>-2</sup> illumination intensity was employed to provide visible-light irradiation. A 420 nm cut-off filter was inserted between the lamp and the sample to filter out UV light ( $\lambda < 420$  nm). Prior to visible-light illumination, the suspension was strongly stirred in dark for 40 min. The solution was then exposed to visible-light irradiation under magnetic stirring. At specific time intervals, 4 mL of the suspension was periodically collected and analyzed after centrifugation. The Rh B concentration was analyzed using a UV-2550 spectrometer to record the intensity of the maximum band at 552 nm in the UV-vis absorption spectra.

### 2.4 Active species trapping experiments

To detect the active species during photocatalytic reactivity, some sacrificial agents such as 2-propanol (IPA), disodium ethylenediamine tetraacetic acid (EDTA-2Na), and 1,4-benzoquinone (BQ) were used as scavengers for hydroxyl radical ( $\cdot\text{OH}$ ), hole ( $h^+$ ), and superoxide radical ( $\text{O}_2^{\cdot-}$ ), respectively. The method was similar to the former photocatalytic activity test with the addition of 1 mmol of quencher in the presence of Rh B.

## 3. Results and discussion

The XRD patterns of SWCNTs, C<sub>60</sub>, and C<sub>60</sub>-CNTs are shown in Fig. 1a. In the diffraction pattern of SWCNTs, an apparent wide peak at  $2\theta = \sim 26^\circ$  appeared, corresponding to the (002) plane.<sup>21</sup> C<sub>60</sub> exhibits diffraction peaks corresponding to (111), (220), (311), and (222) planes at  $2\theta = 10.7^\circ$ ,  $17.7^\circ$ ,  $20.7^\circ$ , and  $21.7^\circ$ , which can be readily indexed to a face centered cubic (fcc) structure (JCPDS no. 44-558).<sup>21</sup> When the two compounds were coupled, the main characteristic diffraction peaks of SWCNTs and C<sub>60</sub> exhibited no obvious change, indicating that C<sub>60</sub> clusters in C<sub>60</sub>-CNTs can form an fcc crystallite. Fig. 1b displays the XRD patterns of the bare Bi<sub>2</sub>MoO<sub>6</sub> and C<sub>60</sub>-CNTs/Bi<sub>2</sub>MoO<sub>6</sub> composite. All the diffraction peaks in the pattern of Bi<sub>2</sub>MoO<sub>6</sub> can be indexed to the specific crystal planes of the Bi<sub>2</sub>MoO<sub>6</sub>

Fig. 1 XRD patterns of SWCNTs, C<sub>60</sub> and C<sub>60</sub>-CNTs (a), Bi<sub>2</sub>MoO<sub>6</sub> and C<sub>60</sub>-CNTs/Bi<sub>2</sub>MoO<sub>6</sub> (b), and BiVO<sub>4</sub> and C<sub>60</sub>-CNTs/BiVO<sub>4</sub> (c).

phase (JCPDS no. 21-0102). Besides the peaks of Bi<sub>2</sub>MoO<sub>6</sub>, the diffraction peaks of C<sub>60</sub> in the pattern of C<sub>60</sub>-CNTs/Bi<sub>2</sub>MoO<sub>6</sub> can be observed, indicating the coexistence of C<sub>60</sub>. Doping with SWCNTs did not significantly change the structure of Bi<sub>2</sub>MoO<sub>6</sub>. It was reported that SWCNTs show a weak but characteristic diffraction peak at 26.0°. However, this peak was not apparent in the patterns of the as-prepared composites, which could be attributed to the small amount of SWCNTs in the composites. In the C<sub>60</sub>-CNTs/BiVO<sub>4</sub> composite, the diffraction peaks of BiVO<sub>4</sub> (JCPDS no. 14-0688) and C<sub>60</sub> were detected (Fig. 1c), suggesting the existence of C<sub>60</sub> and BiVO<sub>4</sub> phases.

Fig. 2 displays the microstructures of C<sub>60</sub>-CNTs/BiVO<sub>4</sub> and C<sub>60</sub>-CNTs/Bi<sub>2</sub>MoO<sub>6</sub>. Usually, the produced SWCNTs have a tendency to form tight bundles.<sup>23,24</sup> C<sub>60</sub>-CNTs are also made of bundles of entangled SWCNTs. As shown in Fig. 2a, the C<sub>60</sub>-CNTs are intimately bound to the leaf-like BiVO<sub>4</sub> nanostructure surfaces. However, some single or double SWCNTs with an average diameter of ~10 nm can still be observed (Fig. 2b). C<sub>60</sub> molecules with a diameter of *ca.* 0.7 nm is too small to be directly resolved by HRTEM observation, which is similar to the reported work.<sup>21</sup> The lattice fringe pattern of BiVO<sub>4</sub> was measured as 0.224 nm (Fig. 2c), consistent with the interplanar spacing of the BiVO<sub>4</sub> (121) plane. A similar phenomenon occurred in the C<sub>60</sub>-CNTs/Bi<sub>2</sub>MoO<sub>6</sub> nanocomposite. As can be seen in Fig. 2d and e the C<sub>60</sub>-CNTs are intimately bound to the surfaces of the Bi<sub>2</sub>MoO<sub>6</sub> nanosheets. The lattice fringe pattern of Bi<sub>2</sub>MoO<sub>6</sub> was measured

as 0.38 nm (Fig. 2f), which is consistent with the interplanar spacing of the Bi<sub>2</sub>MoO<sub>6</sub> (111) plane.

FTIR spectroscopy was applied to distinguish the microstructures of nanostructured carbons and their composites. Fig. 3a shows the FTIR spectra of C<sub>60</sub>, CNTs, C<sub>60</sub>-CNTs, C<sub>60</sub>-CNTs/Bi<sub>2</sub>MoO<sub>6</sub>, and C<sub>60</sub>-CNTs/BiVO<sub>4</sub>. The bands at 1182, 1429, and 1630 cm<sup>-1</sup> are attributed to the internal modes of the C<sub>60</sub> molecule.<sup>25</sup> It can be observed that both C<sub>60</sub>-CNTs/BiVO<sub>4</sub> and C<sub>60</sub>-CNTs/Bi<sub>2</sub>MoO<sub>6</sub> nanocomposites reveal the characteristic bands for C<sub>60</sub> molecule, showing the existence of C<sub>60</sub>-CNTs. The successful loading of C<sub>60</sub>-CNTs was also illustrated by XPS. Fig. 3b displays the deconvolution of the C 1s peaks of C<sub>60</sub>-CNTs, C<sub>60</sub>-CNTs/Bi<sub>2</sub>MoO<sub>6</sub>, and C<sub>60</sub>-CNTs/BiVO<sub>4</sub>. For C<sub>60</sub>-CNTs, the main peak at 282.3 eV was assigned to the sp<sup>2</sup>-hybridized carbon of CNTs, which can be ascribed to the C-C bond of the sp<sup>2</sup>-hybridized carbon in the graphene sheet. In case of C<sub>60</sub>-CNTs/Bi<sub>2</sub>MoO<sub>6</sub> and C<sub>60</sub>-CNTs/BiVO<sub>4</sub>, the binding energy of C 1s shifted by about 0.2 and 0.5 eV, respectively, toward higher binding energies. A similar phenomenon was observed for Bi 4f (Fig. 3c). This implied the successful incorporation of C<sub>60</sub>-CNTs into Bi<sub>2</sub>MoO<sub>6</sub> or BiVO<sub>4</sub>. The spin-orbit of Bi 4f in Bi<sub>2</sub>MoO<sub>6</sub> and BiVO<sub>4</sub> could be well deconvoluted as two peaks at around 159 and 164 eV, which correspond to the Bi 4f<sub>7/2</sub> and Bi 4f<sub>5/2</sub> orbits of Bi<sup>3+</sup>, respectively.

Fig. 4a shows the UV-vis absorption spectra of bare Bi<sub>2</sub>MoO<sub>6</sub>, BiVO<sub>4</sub>, C<sub>60</sub>-CNTs, and C<sub>60</sub>-CNTs/Bi<sub>2</sub>MoO<sub>6</sub>, and C<sub>60</sub>-CNTs/BiVO<sub>4</sub>

Fig. 2 TEM images of as-prepared samples: (a, b)  $C_{60}$ -CNTs/ $BiVO_4$ , (c) HRTEM image of  $C_{60}$ -CNTs/ $BiVO_4$ , (d, e)  $C_{60}$ -CNTs/ $Bi_2MoO_6$ , (f) HRTEM image of  $C_{60}$ -CNTs/ $Bi_2MoO_6$ .

nanocomposites. All the samples exhibit the typical absorptions with an intense transition in the visible region. In addition, the introduction of nanostructured carbons ( $C_{60}$ -CNTs) into the  $Bi_2MoO_6$  or  $BiVO_4$  leads to an increase in absorption in the visible-light region, indicating an intense electronic interaction between the bismuth-based oxide and nanostructured carbon, when  $C_{60}$ -CNTs were used as the carbon source.<sup>21</sup>

In general, for a crystalline semiconductor, the optical absorption band edge can be estimated according to the formula,  $\alpha h\nu = A(h\nu - E_g)^{n/2}$ , where  $\alpha$ ,  $\nu$ ,  $E_g$ , and  $A$  are the absorption coefficient, light frequency, band-gap energy, and a constant, respectively. Among these parameters,  $n$  is determined by the type of optical transition in a semiconductor. The value of  $n$  is 1 for direct transition and 4 for indirect transition. For  $Bi_2MoO_6$  or  $BiVO_4$ , the value of  $n$  is 1 for direct transition, thus, the band gaps were estimated as about 2.34 eV for  $BiVO_4$  and 2.53 eV for  $Bi_2MoO_6$ , as shown in Fig. 4b. In addition, the potentials of the valence band (VB) and conduction band (CB) for  $BiVO_4$  can be calculated according to the two formulas which are proposed by Butler and Ginley:

$$E_{VB} = X - E^e + 0.5E_g \quad (1)$$

$$E_{CB} = E_{VB} - E_g \quad (2)$$

Here,  $E_{VB}$  is the valence band edge potential,  $E_{CB}$  is the conduction band edge potential,  $X$  is the electronegativity of the semiconductor, which is the geometric mean of the electronegativity of the constituent atoms,  $E^e$  is the energy of free electrons on the hydrogen scale (about 4.5 eV), and  $E_g$  is the band gap energy of the semiconductor. Based on the above formulas, the VB potential and CB potential of  $BiVO_4$  were calculated as 2.828 eV and 0.488 eV, respectively, whereas the CB and VB edge potentials of  $Bi_2MoO_6$  were  $-0.26$  eV and 2.27 eV, respectively.

The photocatalytic activities of the samples were evaluated by photocatalytic degradation of a Rh B solution under visible light. Adsorption equilibrium was reached for all the examined photocatalysts after stirring for 40 min in dark (Fig. S1†). As can be seen in Fig. 5a, when the solution is irradiated with visible light for 30 min in the absence of any catalyst, little change in Rh B concentration is observed, which is in agreement with previous reports.<sup>26,27</sup> This indicates that the self-photodegradation of Rh B is negligible. As shown in Fig. 5a, pure  $Bi_2MoO_6$  and  $BiVO_4$  exhibited generally low photocatalytic activities, with only 43.7% and 74.0% Rh B degradation, respectively, after visible-light irradiation for 30 min. This low performance is possibly due to the fast recombination of photo-induced electrons and holes in the single semiconductor. The results indicate that the photocatalytic activity of  $C_{60}$ -CNTs/

Fig. 3 (a) FTIR of as-prepared samples. XPS spectra of as-obtained samples: (b) C 1s, (c) Bi 4f.

bismuth-based oxide nanocomposites toward Rh B is much higher than that of either pure  $\text{Bi}_2\text{MoO}_6$  or  $\text{BiVO}_4$ . The introduction of  $\text{C}_{60}$ -CNTs to bismuth-based oxides resulted in significant improvement in the photocatalytic performances of  $\text{Bi}_2\text{MoO}_6$  and  $\text{BiVO}_4$ . After 30 min of visible-light irradiation, the photocatalytic degradation percentages of Rh B were about 96.1% and 88.4% for  $\text{C}_{60}$ -CNTs/ $\text{BiVO}_4$  and  $\text{C}_{60}$ -CNTs/ $\text{Bi}_2\text{MoO}_6$  composites, respectively. This is because the efficient hetero-junction interface between two or three components can restrain the recombination of photo-induced charges effectively.<sup>28,29</sup> The  $\text{C}_{60}$ -CNTs coating can improve the visible-light absorption efficiency (Fig. 4), which is beneficial for the ternary composite in photolyzing Rh B.<sup>30,31</sup> Further, the surface

areas of the samples were measured by  $\text{N}_2$  adsorption-desorption isotherms. Fig. 5b shows the  $\text{N}_2$  adsorption-desorption isotherms at 77 K. The obtained BET specific surface areas for  $\text{BiVO}_4$ ,  $\text{Bi}_2\text{MoO}_6$ ,  $\text{C}_{60}$ -CNTs,  $\text{C}_{60}$ -CNTs/ $\text{BiVO}_4$ , and  $\text{C}_{60}$ -CNTs/ $\text{Bi}_2\text{MoO}_6$  samples are 20.913, 44.202, 188.426, 146.071, and 179.465  $\text{m}^2 \text{g}^{-1}$ , respectively (Table 1). It can be observed that the BET specific areas increased after the loading of  $\text{C}_{60}$ -CNTs, which can facilitate more efficient contact of the composite samples with organic contaminants, leading to the enhancement of photocatalytic efficiency.<sup>32,33</sup> Because a renewable catalyst is another important criterion for photocatalytic application,<sup>34</sup> the stabilities of  $\text{C}_{60}$ -CNT/ $\text{Bi}_2\text{MoO}_6$  and  $\text{C}_{60}$ -CNTs/ $\text{BiVO}_4$  composites were investigated by a recycling test (Fig. 5c).

Fig. 4 (a) UV-vis absorption spectra of the as-obtained samples. (b) Plots of  $(\alpha h\nu)^2$  versus photon energy ( $h\nu$ ) for the band gap energies of  $\text{BiVO}_4$  and  $\text{Bi}_2\text{MoO}_6$ .

Fig. 5 (a) Photodegradation efficiencies of Rh B as a function of irradiation time for different photocatalysts. (b)  $\text{N}_2$  adsorption–desorption isotherm curves of the as-prepared samples. (c) Cycling runs for photocatalytic degradation of Rh B over the ternary nanocomposites under visible-light irradiation. (d) Trapping experiment of active species during photocatalytic degradation of Rh B over  $\text{C}_{60}\text{CNTs/bismuth-based oxide nanocomposites}$  under visible-light irradiation.

After four cycles, there was no significant loss of activity, which indicated that the composite photocatalysts were stable during the photocatalytic test.

To further probe the underlying mechanism of the ternary nanocomposites, different scavengers for the various active species were added into the reaction system. In particular, IPA, BQ, and EDTA-2Na were used to capture  $\cdot\text{OH}$ ,  $\cdot\text{O}^{2-}$ , and  $\text{h}^+$ , respectively. As shown in Fig. 5d, the photocatalytic performance of  $\text{C}_{60}\text{-CNTs/Bi}_2\text{MoO}_6$  toward Rh B degradation was clearly inhibited by the addition of EDTA-2Na and BQ. Similar results were observed with the trapping of active species during the photocatalytic degradation of Rh B over  $\text{C}_{60}\text{-CNTs/BiVO}_4$ . These results indicate that  $\cdot\text{O}^{2-}$  and  $\text{h}^+$  play critical roles in the photocatalytic degradation of Rh B for the ternary composites.

The possible photocatalytic mechanism of the  $\text{C}_{60}\text{-CNTs/Bi}_2\text{MoO}_6$  nanocomposite is illustrated in Fig. 6. First, the large specific surface areas of the ternary nanocomposite and its enhanced adsorption ability toward the contaminants contribute to the photocatalytic process. Particularly, the loading of  $\text{C}_{60}\text{-CNTs}$  promotes the visible-light absorption of  $\text{Bi}_2\text{MoO}_6$ , which enables photoexcitation of more electrons from the VB to the CB.<sup>21</sup> Further, the small  $\text{C}_{60}$  molecules can serve as an efficient electron reservoir to capture the photogenerated electrons, thus hindering the recombination of electron–hole carriers.<sup>22</sup> Meanwhile, CNTs can also help to suppress the charge recombination by capturing the photogenerated electrons owing to their excellent electron conductivity and mobility.<sup>23</sup> On the other hand, owing to the formation of

Table 1 BET specific surface area of the as-prepared samples

Photocatalysts	BET specific surface area ( $\text{m}^2 \text{g}^{-1}$ )	Photocatalysts	BET specific surface area ( $\text{m}^2 \text{g}^{-1}$ )
$\text{BiVO}_4$	20.913	$\text{C}_{60}\text{-CNTs/BiVO}_4$	146.071
$\text{Bi}_2\text{MoO}_6$	44.202	$\text{C}_{60}\text{-CNTs/Bi}_2\text{MoO}_6$	179.465
$\text{C}_{60}/\text{CNTs}$	188.426		

Fig. 6 Schematic diagram of the separation and transfer of photogenerated charges in the  $C_{60}$ -CNTs/ $Bi_2MoO_6$  composite photocatalyst under visible-light irradiation.

heterojunctions between  $C_{60}$ -CNTs and  $Bi_2MoO_6$  and their intimate interfacial interaction, photogenerated electrons can efficiently transfer to  $C_{60}$  and CNTs, thus showing enhanced separation efficiency for the photogenerated electron–hole pairs. In this way, the excited electrons participate in the reduction of  $O_2$  to  $\cdot O_2^-$ . Subsequently, the  $\cdot O_2^-$  and holes on the valence band of  $Bi_2MoO_6$  oxidize the Rh B to  $CO_2$  and  $H_2O$ .

## 4. Conclusions

In this study,  $C_{60}$ -decorated SWCNTs ( $C_{60}$ -CNTs) were prepared by a solution method. Thereafter, novel nanostructured carbon/bismuth-based oxide nanocomposites were successfully synthesized *via* a facile hydrothermal method with nanostructured carbons. These nanostructured carbon/bismuth-based oxide nanocomposites are beneficial for improving the photocatalytic efficiency. The enhanced performance is due to the extended absorption in the visible-light region resulting from  $C_{60}$ -CNTs loading, high specific surface area, and efficient separation of electron–hole pairs by the ternary composite system. This study suggests that the  $C_{60}$ -CNTs, as a new carbon nanostructured material, can be employed as an effective co-catalyst for photocatalytic application.
