A mitochondria-targeting ratiometric fluorescent probe for the detection of hypochlorite based on the FRET strategy†

Shi-Li Shen, ^{*a} Xiao-Fan Zhang,^b Yan-Qing Ge, ^a Yan Zhu^a
and Xiao-Qun Cao ^{*a}

In this study, a ratiometric fluorescent probe (IRP) for OCl^- was designed based on the fluorescence resonance energy transfer (FRET) platform. The probe was fabricated by integrating an imidazo[1,5-*a*]pyridine moiety (donor) with a rhodamine moiety (acceptor). We evaluated its properties for recognizing OCl^- and the results implied that IRP possessed high selectivity, a real-time detection possibility and brilliant photostability. The fluorescence intensity ratios (I_{575}/I_{467}) of IRP displayed desirable OCl^- -dependent performance and responded linearly to OCl^- in the concentration range of 0.5–3.5 μM . Also, IRP was applied to image endogenous OCl^- with a mitochondria-targeting ability, due to the introduction of the quaternized pyridine moiety. Therefore, IRP may be used for further mitochondrial OCl^- -related studies.

Introduction

Reactive oxygen species (ROS) are of scientific interest since they could mediate a number of biological processes. Hypochlorous acid (HOCl)/hypochlorite (OCl^-), one of the most important ROS, has received increasing attention recently. OCl^- is synthesized from hydrogen peroxide and chloride with the aid of myeloperoxidase (MPO) in immunological cells.¹ OCl^- is a powerful oxidizer with effective antibacterial properties when microorganism infections occur.² Despite that, the abnormal generation of OCl^- *in vivo* may be harmful and is implicated in various diseases such as rheumatoid arthritis, atherosclerosis, osteoarthritis and lung injury.^{3–6} Thus, scientists have devoted effort to developing sensitive and accurate methods to detect OCl^- . Among the analytical methods, fluorescent probes show many advantages in terms of sensitivity and selectivity as well as spectral resolution.^{7–18} Single emission-based probes are flawed in quantitative assays, because the results may be perturbed by environmental factors. Ratiometric probes, which can normalize the interference, have been a powerful approach for recognizing and detecting OCl^- .^{19,20}

Fluorescence resonance energy transfer (FRET) strategy is an effective approach to constructing ratiometric probes.

FRET-based probes for OCl^- display two well-resolved emission peaks before and after reaction with OCl^- .^{21–23} However, despite the good performance, it is difficult to construct such an FRET-based system on account of the prerequisite of substantial spectral overlap between donor emission and acceptor absorption. Hence, it is highly desirable to develop novel fluorophores for the fabrication of FRET-based probes.

By far, clarifying the intracellular functions of OCl^- is still a challenge since the subcellular distribution of OCl^- is uncertain. So it is highly urgent to fabricate fluorescent probes for OCl^- possessing organelle-targeting ability. To the best of our knowledge, some organelle-targeting probes for OCl^- have been developed.^{24–28} However, OCl^- ratiometric probes based on FRET that can be applied especially in mitochondria are still in great demand.^{23,29}

Previously we designed a ratiometric probe for sensing copper ion based on imidazo[1,5-*a*]pyridine-rhodamine FRET system.³⁰ The data indicated that emission spectrum of imidazo[1,5-*a*]pyridine and absorption spectrum of rhodamine largely overlapped, thus giving efficient FRET process. Inspired by this, we chose imidazo[1,5-*a*]pyridine as FRET donor and rhodamine as FRET acceptor to produce a OCl^- ratiometric probe (IRP). IRP exhibited high selectivity and sensitivity toward OCl^- . In comparison with other OCl^- probes, probe IRP showed much lower detection limit (10.2 nM).^{31–34} Moreover, quaternized pyridine moiety, which was a mitochondria-targeting group, was introduced into the probe to achieve mitochondria-targeting ability.^{6,23,29} IRP has also been applied for fluorescence imaging of endogenous OCl^- with excellent membrane permeability and stability.

Results and discussion

Design and synthesis of probe IRP

The imidazo[1,5-*a*]pyridine fluorophore was chosen as the FRET donor due to its outstanding spectroscopic properties.^{35–37} And rhodamine moiety was selected as FRET acceptor, because the emission spectra of imidazo[1,5-*a*]pyridine and the excitation spectra of rhodamine largely overlapped, which was essential for an efficient energy transfer process. Importantly, the quaternized pyridine moiety was introduced into probe **IRP** to realize the mitochondria-targeting capability. We expected that the quaternized pyridine moiety in probe **IRP** would enable the probe to be suitable for the fluorescence imaging of endogenous [−]OCl in mitochondria.

Probe **IRP** was synthesized *via* a simple process (Scheme 1) and characterized by ¹H NMR, ¹³C NMR and HRMS (Fig. S1–S3, ESI†).

Spectroscopic response of probe IRP to [−]OCl

The absorption spectra of **IRP** were investigated in EtOH-PBS (3/7, v/v, pH 7.4). As shown in Fig. 1, **IRP** exhibited a maximal absorption band at 365 nm, which was assigned to the imidazo[1,5-*a*]pyridine moiety. And the absorbance was almost unchanged along with [−]OCl addition. Upon addition of [−]OCl, a new absorption peak appeared at 555 nm and the absorbance increased remarkably. The spectra changes could be attributed to the structural formation of ring-opened form of rhodamine moiety, induced by the reaction of **IRP** and [−]OCl.

To explore the fluorescence response of **IRP** to [−]OCl, probe **IRP** was titrated with various concentrations of [−]OCl (Fig. 2a). Upon excitation at 370 nm, the probe only emitted the fluorescence of imidazo[1,5-*a*]pyridine moiety (467 nm). When [−]OCl was titrated from 0 to 5 μM, the emission peak of imidazo[1,5-*a*]pyridine decreased. Meanwhile, a typical emission peak of rhodamine moiety emerged at 575 nm and the fluorescence intensity increased gradually, which was in perfect agreement with the absorption spectra changes. The phenomena could be ascribed to the energy transfer between imidazo[1,5-*a*]pyridine donor and rhodamine acceptor (Scheme 2). The rhodamine moiety was in the ring-closed form in the absence of [−]OCl, and no FRET was found in probe **IRP** at this stage. However, the titration of [−]OCl resulted in the rhodamine structural transformation from spirolactam form (non-fluorescent) to ring-opened form (fluorescent). The HRMS spectra of the reaction

Fig. 1 Absorption spectra of probe **IRP** (5 μM) upon addition of [−]OCl.

mixture of **IRP** with [−]OCl (Fig. S4†) verified the structure change of rhodamine moiety. And the ring-opened rhodamine moiety was an efficient energy acceptor. FRET process between imidazo[1,5-*a*]pyridine donor and rhodamine acceptor occurred accordingly. The energy transfer efficiency was determined to be 45%.

Fluorescence intensity ratios (I_{575}/I_{467}) as a function of [−]OCl concentration were illustrated in Fig. 2b. When the [−]OCl concentration increased from 0 to 5 μM, I_{575}/I_{467} exhibited a significant enhancement. More importantly, the inset indicated that there was a linear correlation between the fluorescence intensity ratio (I_{575}/I_{467}) and the [−]OCl concentration from 0.5 to 3.5 μM ($R = 0.998$). In addition, the limit of detection was calculated to be 10.2 nM, which demonstrated that probe **IRP** may be able to monitor [−]OCl changes at trace levels.

In order to investigate whether the probe could selectively respond to [−]OCl, we evaluated the influence of potential interferents, including ROS/RNS and common ions. As shown in Fig. 3, compared to other tested analytes, only the presence of [−]OCl caused a dramatic increase of I_{575}/I_{467} for the probe **IRP**. The results indicated that the probe possessed excellent selectivity for [−]OCl even in the complicated intracellular environment.

The effect of solution pH on the fluorescence response of **IRP** toward [−]OCl was also studied (Fig. 4). Probe **IRP** itself was stable

Scheme 1 Synthesis of probe **IRP**.

Fig. 2 (a) Fluorescence titration spectra and (b) fluorescence intensity ratios (I_{575}/I_{467}) of probe **IRP** (2 μM) upon addition of [−]OCl. The inset showed the linear relationship of intensity ratios (I_{575}/I_{467}) along with [−]OCl concentration ($R = 0.998$).

Scheme 2 Proposed mechanism of IRP for sensing OCl^- .

in the pH range of 4.0–10.0. After OCl^- (2 μM) was added to the **IRP** solution, the fluorescence intensity ratio (I_{575}/I_{467}) increased notably and peaked at pH 7.4, implying that **IRP** could be used to detect OCl^- in neutral and slightly basic conditions. Since the pK_a of HOCl was 7.6, we speculated that the probe could sense OCl^- rather than HOCl . In consideration of the weakly basic pH conditions in mitochondria, we anticipated that **IRP** may be suitable for mitochondrial OCl^- measurement.

Furthermore, the time courses of **IRP** were recorded upon addition of OCl^- (3 μM). As displayed in Fig. S5,† the fluorescence intensity ratios (I_{575}/I_{467}) of **IRP** instantly increased and reached a plateau after OCl^- was added to the solution. Hence, the probe was able to sense OCl^- rapidly, which was pivotal for the real-time detection of OCl^- . The high specificity of **IRP** for OCl^- over other species, fast response, as well as the satisfactory OCl^- -dependent performance further confirmed that probe **IRP** had great potential as a practical tool for OCl^- detection *in vivo*.

Cell imaging of probe IRP

In light of the excellent spectroscopic response of probe **IRP** toward OCl^- *in vitro*, we proceeded to explore the biological application of cell imaging. Murine RAW264.7 cells were selected to image endogenous HOCl in living cells, since RAW264.7 cells would produce HOCl after the stimulation with lipopolysaccharide (LPS).²³ After RAW264.7 cells were incubated with **IRP** (1 μM)

Fig. 4 Fluorescence intensity ratios (I_{575}/I_{467}) of **IRP** (2 μM) versus pH in the absence (●) or presence (■) of OCl^- (2 μM).

for 30 min, bright blue fluorescence and weak red fluorescence were noticed, as shown in Fig. 5a. Whereas in the experiment group, RAW264.7 cells were incubated with LPS for 6 h and then with phorbol 12-myristate 13-acetate (PMA) for 30 min, followed by incubation with probe **IRP** (1 μM) for 30 min. According to the previous papers, the synergistic effect of LPS and PMA could stimulate RAW264.7 cells to produce HOCl .^{38–41} The blue fluorescence turned weaker and the red fluorescence became stronger, compared to the control group without LPS. Moreover, the fluorescence intensity ratio (blue to red) declined obviously in the presence of LPS (Fig. 5b). The results suggested that probe **IRP** could sense endogenous OCl^- in living cells.

To further determine the subcellular localization of **IRP**, the commercially available mitochondrial dye, Mito Tracker Deep Red, was utilized for the co-localization study (Fig. 6). RAW264.7 cells were incubated with the probe (1 μM) for 30 min and then with Mito Tracker Deep Red (0.2 μM) for 30 min. The imidazo [1,5-*a*]pyridine signals in **IRP**-loaded cells overlapped significantly with the signals of Mito Tracker Deep Red (Fig. 6c) and the co-localization coefficient was calculated to be 0.95. The

First line: the cells incubated with **IRP** (1 μM) for 30 min, second line: the cells treated with LPS (1 $\mu\text{g mL}^{-1}$) for 6 h, then with PMA (1 $\mu\text{g mL}^{-1}$) for 30 min and with **IRP** (1 μM) for 30 min. First column: imidazo[1,5-*a*]pyridine fluorescence (410–520 nm), second column: rhodamine fluorescence (560–700 nm), third column: overlap images of the first and second columns, fourth column: bright field images. (b) Fluorescence intensity quantitation was analyzed using the Image J. The results were presented as mean \pm SE with replicates $n = 3$.

Fig. 6 Fluorescence images of RAW264.7 cells co-stained with IRP (1 μ M) and Mito Tracker Deep Red (0.2 μ M). (a) Imidazo[1,5-*a*]pyridine fluorescence of IRP. (b) Fluorescence of Mito Tracker Deep Red. (c) Overlay of (a) and (b). (d) Bright field images.

results indicated that IRP could selectively stain mitochondria. In addition, we also conducted the co-localization assays of IRP with Lyso Tracker Deep Red. After RAW264.7 cells were incubated with IRP (1 μ M) for 30 min and then with Lyso Tracker Deep Red (0.2 μ M) for 30 min, the cells were imaged. As depicted in Fig. S6,[†] the probe was not site-specifically internalized in lysosomes (co-localization coefficient: 0.20). Therefore, the co-localization data confirmed that probe IRP could target mitochondria.

Considering that a probe's cytotoxicity and photostability were vital parameters for the cellular bio-imaging, so we next evaluated the cytotoxicity of IRP by standard SRB assays. Fig. S7[†] revealed that the cell viability was affected little after incubation with IRP (1, 2, 4, 6 μ M) for 12 h. Furthermore, the photostability property of the probe was inspected and the results implied that probe IRP exhibited satisfactory photostability within 120 s under the experimental conditions (Fig. S8[†]).

Experimental

Apparatus and chemicals

^1H NMR (400 MHz) and ^{13}C NMR (100 MHz) spectra were acquired on a Bruker Avance spectrometer, with d_6 -DMSO used as a solvent and tetramethylsilane (TMS) as an internal standard. High-resolution mass spectroscopy (HRMS) was collected on a Q-TOF6510 spectrograph (Agilent). UV-vis spectra were measured by a Hitachi U-4100 spectrophotometer. Fluorescent measurements were performed on a Perkin-Elmer LS-55 luminescence spectrophotometer. The pH was determined with a model PHS-3C pH meter (YouKe, Shanghai, China).

^-OCl solution was prepared by diluting the commercially available NaOCl solution. ROS and reactive nitrogen species (RNS) solutions were prepared by the literature.^{42–44} Unless otherwise stated, all reagents were used without further purification from merchants. Twice-distilled water was used throughout all experiments.

Preparation of test solutions

Probe IRP was dissolved in ethanol to afford the stock solution (10^{-4} M). All analysis samples were prepared by displacing the stock solution into a 10 mL volumetric flask. The solution was diluted to 10 mL in a mixture solution of EtOH-PBS (pH 7.4) = 3 : 7, v/v. Appropriate aliquots of each testing species solution were then added. The resulting solutions were shaken well and incubated for 30 min before measurements.

Synthesis of probe IRP

The synthetic route of probe IRP was displayed in Scheme 1, in which compound 1 was prepared according to our previous work.³⁰ Compound 1 (1.0 mmol) was dissolved in dry dichloromethane (20 mL) and triethylamine (3.3 mmol). The solution was cooled to 0 $^{\circ}\text{C}$ with stirring under nitrogen atmosphere. Then, chloroacetyl chloride (3.0 mmol) was added dropwise to the solution. After addition, the reaction was stirred at 0 $^{\circ}\text{C}$ for 4 h. Subsequently, the solvent was removed under reduced pressure to give compound 2. The crude product was used for next step without purification.

Compound 2 (1.0 mmol) and pyridine (1 mL) were dissolved in anhydrous acetonitrile (30 mL). The solution was refluxed overnight. Then the solvent was removed under reduced pressure and the crude product was purified by column chromatography on silica gel using dichloromethane/methanol (10/1, v/v) as the eluent to obtain IRP as a faint yellow solid (yield: 49.6%). ^1H NMR (400 MHz, d_6 -DMSO), δ (ppm): 0.92 (t, 3H, J = 7.6 Hz, CH_3), 1.09 (t, 6H, J = 6.8 Hz, CH_3), 1.32 (q, 2H, J = 7.6 Hz, CH_2), 1.68–1.73 (m, 2H, CH_2), 2.92 (t, 2H, J = 7.4 Hz, CH_2), 3.26 (br, 4H, CH_2), 3.32 (br, 4H, CH_2), 3.68 (br, 4H, CH_2), 5.48 (s, 2H, CH_2), 6.34 (d, 2H, J = 9.2 Hz, ArH), 6.49 (d, 1H, J = 8.8 Hz, ArH), 6.56–6.61 (m, 2H, ArH), 6.68 (d, 1H, J = 2.0 Hz, ArH), 6.75 (d, 1H, J = 7.2 Hz, ArH), 7.05 (d, 1H, J = 6.8 Hz, ArH), 7.52 (s, 1H, ArH), 7.54–7.62 (m, 2H, ArH), 7.85 (d, 1H, J = 6.8 Hz, ArH), 8.14–8.17 (m, 2H, ArH), 8.29 (d, 1H, J = 7.2 Hz, ArH), 8.70 (t, 1H, J = 8.0 Hz, ArH), 8.74 (d, 2H, J = 5.6 Hz, ArH), 10.60 (s, 1H, NH). ^{13}C NMR (100 MHz, d_6 -DMSO), δ (ppm): 167.6, 164.2, 163.8, 153.4, 153.1, 151.8, 151.7, 149.0, 146.9, 146.1, 138.9, 134.1, 129.5, 129.4, 129.2, 128.5, 128.2, 126.4, 124.3, 123.7, 123.3, 122.8, 118.7, 115.9, 112.4, 111.7, 108.5, 108.4, 104.1, 101.9, 97.5, 65.5, 60.6, 47.9, 44.1, 29.4, 29.1, 25.6, 22.1, 14.1, 12.9. HRMS m/z : calcd for $\text{C}_{47}\text{H}_{48}\text{ClN}_8\text{O}_4\text{S}$ [M]⁺: 823.3487; found: 823.3552. m/z : calcd for $\text{C}_{47}\text{H}_{49}\text{ClN}_8\text{O}_4\text{S}$ [$\text{M} + \text{H}$]²⁺/2: 412.1782; found: 412.1790.

Cell culture and imaging

RAW264.7 cells (ATCC® TIB-71™) were cultured in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% (v/v) fetal bovine serum in an atmosphere containing 5% CO_2 and 95% air at 37 $^{\circ}\text{C}$. The cells were imaged using confocal fluorescence microscopy (Leica SP8).

Conclusion

In summary, we employed imidazo[1,5-*a*]pyridine-rhodamine FRET platform to develop a ratiometric fluorescent probe for ^-OCl . The probe was able to detect ^-OCl selectively and function well in mitochondrial physiological pH conditions. I_{575}/I_{467} ratios of the probe responded linearly to minor fluctuations of ^-OCl concentration (0.5–3.5 μM). Moreover, the probe was applied to sense endogenous ^-OCl in RAW264.7 cells with negligible toxicity. In particular, the probe could target mitochondria due to the introduction of the quaternized pyridine moiety. Hence, we expected that the probe would be a promising candidate for highly selective and sensitive sensing of ^-OCl in mitochondria.
