Enantioselective [2 + 2] cycloaddition of *N*-allenamides with cyclic *N*-sulfonylketimines: access to polysubstituted azetidines bearing quaternary stereocenters†

Ren-Rong Liu, Jiang-Ping Hu, Jian-Jun Hong, Chuan-Jun Lu, Jian-Rong Gao and Yi-Xia Jia*

A $\text{Ni}(\text{ClO}_4)_2$ -catalyzed enantioselective [2 + 2] cycloaddition of *N*-allenamides with cyclic *N*-sulfonylketimines was developed, which regioselectively occurred at the proximal $\text{C}=\text{C}$ bonds of the *N*-allenamides. Broad substrate scope of *N*-allenamides and cyclic *N*-sulfonylketimines was observed. A range of fused polysubstituted azetidines bearing quaternary stereocenters were afforded in good yields and with excellent enantioselectivities (up to 99%).

N-Allenamides are readily available allenic scaffolds and valuable building blocks in organic synthesis, and therefore have received considerable attention in the past decades.^{1,2} Significant effort has been devoted to the cycloaddition reactions of *N*-allenamides,³ and several enantioselective [n + 2] reactions have been explored as reliable approaches to synthesise a diverse array of carbo- or heterocyclic substructures (Scheme 1).^{4–6} Mascareñas *et al.* developed an elegant enantioselective intermolecular [4 + 2] cycloaddition reaction between *N*-allenamides and dienes using a gold/chiral carbene catalyst (Scheme 1a).⁴ González's and Zhang's groups disclosed [2 + 2] cycloadditions of *N*-allenamides with olefins, leading to optically active cyclobutanes with excellent enantioselectivities (Scheme 1b).^{5a,c} Interestingly, in the latter case a dearomatic [4 + 2] reaction of 3-styrylindoles was observed by varying indolic *N*-substituents.^{5c} A dearomatic [2 + 2] cycloaddition reaction of *N*-allenamides with indoles was realized by Bandini's group as a powerful route to access cyclobutane-fused indolines with excellent enantioselectivities.^{5b} The [3 + 2] reaction was also developed by Chen and co-workers in an enantioselective cycloaddition of *N*-allenamides with nitrones (Scheme 1c).^{6a} It should be noted that all of the above reactions mainly relied on *N*-allenamide activation to form an α,β -unsaturated imine intermediate and hence regioselectively occurred at its distal $\text{C}=\text{C}$ bond. In sharp contrast, the reactivity of *N*-allenamide at the proximal $\text{C}=\text{C}$ bond has remained rarely studied.⁷ The only enantioselective example was reported by

Zhang's group in an asymmetric [3 + 2] reaction involving *in situ* annulation of yne-enones (Scheme 1d).^{6b} Meanwhile, all of the precedent examples exclusively relied on chiral noble gold catalysts. Moreover, despite these advances, no example of cycloaddition of *N*-allenamides with imines has appeared for the synthesis of nitrogen-bearing four-membered heterocycles even in their racemic version.^{1a} Therefore, the development of

Scheme 1 Reactivity of *N*-allenamides in enantioselective cycloaddition reactions.

new cycloaddition reactions of *N*-allenamides and a new catalyst system to synthesize important heterocyclic cores is highly attractive.

Azetidine derivatives are important entities in organic chemistry and are frequently occurring scaffolds in natural products and bioactive molecules. Enantioselective [2 + 2] reaction of imines provides a straightforward route to such strained four-membered heterocycles, including β -lactams.^{8,9} However, as a unique building block, *N*-allenamide has not been utilized in the [2 + 2] cycloaddition with imines. We envisioned that an enantioselective [2 + 2] cycloaddition of *N*-allenamides with imines might occur *via* an imine activation strategy using a chiral Lewis acid catalyst, where *N*-allenamide acts as a nucleophile (like enamide) to attack the imine at its more electron-rich proximal C=C bond and hence delivers highly substituted azetidines through the cyclization that follows.¹⁰ Herein, we report the first enantioselective [2 + 2] cycloaddition reaction of *N*-allenamides with cyclic *N*-sulfonyl α -ketiminoesters¹¹ to afford fused polysubstituted chiral azetidines bearing quaternary stereocenters with excellent enantioselectivities (Scheme 1e). A non-noble chiral nickel catalyst was applied for the first time in the cycloaddition reactions of *N*-allenamides.

Our study began with the model reaction between *N*-allenamide **1a** and cyclic α -ketiminoester **2a**. Pleasingly, an initial test revealed that the complex of $\text{Ni}(\text{ClO}_4)_2 \cdot 6\text{H}_2\text{O}$ /chiral bisoxazoline **L1** smoothly promoted the reaction in DCE and in the presence of 4 Å molecular sieves at room temperature, resulting in the desired product **3aa** in 83% yield, albeit with a poor ee value (Table 1, entry 1). Subsequent ligand examination implied that chiral substituents of oxazoline were critical to enantioselectivity (entries 2–7). Ligands **L2**–**L3** bearing isopropyl or *tert*-butyl substituents led to poor enantioselectivities (entries 2 and 3), while **L4**, containing phenyl substituents, was the best choice to give **3aa** in 99% ee and 82% yield (entry 4).¹² Inferior results were obtained when **L5** and **L6** bearing *trans*- or *cis*-diphenyl substituents were used (entries 5 and 6). Phosphine ligand **L7** led to **3aa** with a moderate yield and ee value (entry 7). Solvent investigation showed that excellent enantioselectivities with relatively lower yields were observed in CH_2Cl_2 , THF, and toluene (entries 8–10). Either poor yield or poor enantioselectivity was obtained in Et_2O or MeCN (entries 11 and 12). Changing the Lewis acid to $\text{Cu}(\text{OTf})_2$ or $\text{Mg}(\text{OTf})_2$ resulted in an almost racemic product (entries 13 and 14), while $\text{Zn}(\text{OTf})_2$ led to a relatively lower ee (entry 15). Other perchlorate metal salts, such as $\text{Mg}(\text{ClO}_4)_2$, $\text{Zn}(\text{ClO}_4)_2 \cdot 6\text{H}_2\text{O}$, and $\text{Cu}(\text{ClO}_4)_2 \cdot 6\text{H}_2\text{O}$, were also tested and inferior results were obtained (entries 16–18). Finally, a poor yield was obtained in the absence of 4 Å MS due to the decomposition of *N*-allenamide **1a** (entry 19). It is noteworthy that only one isomer was detected in these reactions.

With the optimal reaction conditions found, we then investigated the scope of *N*-allenamides **1** and *N*-sulfonyl α -ketiminoesters **2**. As shown in Table 2, α -ketiminoesters **2a**–**2d**, bearing different ester groups, were first evaluated. Good yields and enantioselectivities were afforded in these reactions in spite of a slightly decreased ee value for the iso-propyl substrate **2b**.

(entries 1–4). Substituents attached at the C5–C7 position of the α -ketiminoesters were then investigated (entries 5–14). The substituted groups, such as halide, $-\text{CF}_3$, $-\text{OCF}_3$, $-\text{OMe}$, and alkyl groups, were well tolerated to afford the corresponding products with excellent enantioselectivities and modest to good yields. The reaction yields of the α -ketiminoesters containing electron-donating substituents were slightly higher than those of the α -ketiminoesters bearing electron-deficient substituents (entries 5–7 vs. 8–11).

^a Reaction conditions are identical to those in entry 4 in Table 1.^b Isolated yield of the only isomer. ^c Determined by chiral HPLC.

The scope of *N*-allenamide 4 was also evaluated. By varying the aryl substituents and the sulfonyl groups, a number of substituted *N*-allenamides were tested and afforded the expected products in good yields and with excellent ee values (entries 15–26). It is worth noting that the reaction of *N*-benzyl substrate 1e also produced the desired azetidine 3ea in 71% yield and 99% ee (eqn (1)). Moreover, a racemic 3-substituted *N*-allenamide 1l was also used in this reaction to give the desired product 3la in 75% yield and 95% ee (eqn (2)). Interestingly, a kinetic resolution process of *N*-allenamide 1l was observed and the remaining starting material was isolated in 70% yield and 68% ee, which represents a promising route to chiral *N*-allenamide.¹³ In addition, *N*-allenyl pyrrolidinone 4a and oxazolidinone 4b were also tested as substrates in this transformation, however, acrylaldehyde 5a was isolated as the major product instead of the desired cycloaddition adduct (Scheme 2). Although a poor yield of 5a was obtained for the reaction of 4a, the yield and ee were both remarkably improved by employing *N*-oxazolidinone 4b as the substrate. Several other α -ketiminoesters were then examined in the reactions with 4b

Scheme 2 Reaction of *N*-allenyl pyrrolidinone 4a and oxazolidinone 4b with α -ketiminoesters.

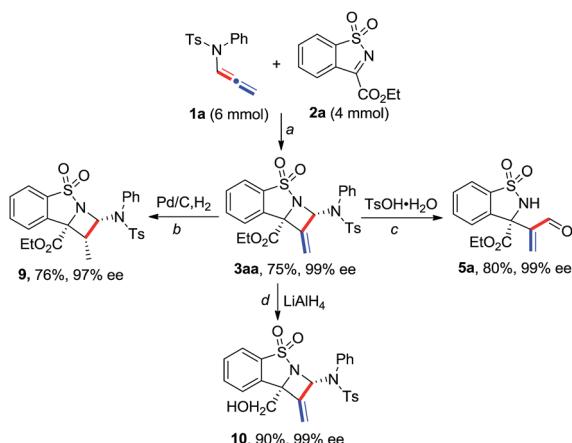

to afford the corresponding acrylaldehydes 5b–5e in acceptable yields and with good to excellent enantioselectivities.

Cyclic six-membered *N*-sulfonyl α -ketimines were also examined as substrates in this reaction. The desired [2 + 2] adducts 7a and 7b were afforded with good yields and enantioselectivities (Scheme 3). In the case of a naphthyl-ketimine substrate, the pure adduct could not be obtained; however, acrylaldehyde 8c was isolated in 63% yield and with 82% ee by treating the mixture with 10 mol% TsOH after the reaction.

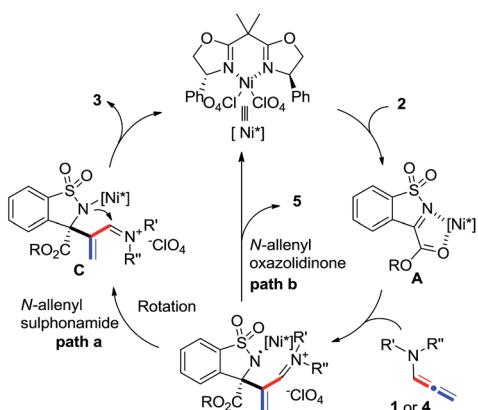

A gram-scale reaction of 1a with 2a was carried out to afford product 3aa in 75% yield and 99% ee, showing good reliability of the present process (Scheme 4). Synthetic transformations of 3aa were then performed. A Pd/C-catalyzed hydrogenation of 3aa afforded saturated azetidine 9 as a single isomer in 76% yield and 97% ee. Reduction of 3aa in the presence of LiAlH₄ led to homoallylic alcohol 10 in 90% yield and 99% ee. TsOH-catalyzed hydrolysis of 3aa afforded acrylaldehyde 5a in 80% yield without any loss of enantioselectivity.

A tentative stepwise mechanism that accounts for the [2 + 2] reaction is proposed in Scheme 5. α -Ketiminoester 2 is firstly activated by the chiral nickel catalyst in a 1,4-binding coordination fashion to form intermediate A. Subsequent enantioselective nucleophilic addition of *N*-allenamide 1 or 4 to A generates intermediate B. The [2 + 2] product 3 was then regioselectively formed by the intramolecular cyclization of the

Scheme 3 Reaction of *N*-allenamide 1a with cyclic six-membered *N*-sulfonylketimines 6.

Scheme 4 Gram-scale reaction and synthetic transformations of product **3aa**. ^a Conditions are identical to those in entry 4 in Table 1; ^b Pd/C (10 mol%), H₂ (1 atm) in MeOH (0.1 M) at 25 °C for 1 h; ^c TsOH·H₂O (10 mol%) in DCE (0.2 M) at 60 °C for 3 h; ^d LiAlH₄ (2.0 equiv.) in THF (0.1 M) at 25 °C for 1 h.

Scheme 5 Proposed reaction pathway.

amide with iminium (path a) and the catalyst was released simultaneously. The formation of acrylaldehyde **5** instead of the [2 + 2] adduct is probably owing to the hydrolysis of intermediate **B** when employing *N*-allenyl oxazolidinone **4b** as the substrate (path b).

Conclusions

In summary, we have developed a novel catalytic enantioselective [2 + 2] cycloaddition reaction of *N*-allenamides with cyclic *N*-sulfonyl α -ketiminoesters, which delivered a range of polysubstituted chiral azetidines bearing quaternary stereocenters as valuable bioactive compounds in good yields and with excellent enantioselectivities. The complex of Ni(ClO₄)₂ with commercially available chiral bisoxazoline ligands was utilized for the first time as a chiral catalyst in the cycloaddition reaction of *N*-allenamides. Broad substrate scope was observed for allenamides and cyclic *N*-sulfonylketimines. It is noteworthy

that acrylaldehyde products were obtained when employing *N*-allenyl oxazolidinones as substrates.

11 For selected examples of enantioselective transformations of cyclic *N*-sulfonylketimines, see: (a) T. Nishimura, A. Noishiki, G. C. Tsui and T. Hayashi, *J. Am. Chem. Soc.*, 2012, **134**, 5056; (b) Y. Luo, A. J. Carnell and H. W. Lam, *Angew. Chem., Int. Ed.*, 2012, **51**, 6762; (c) H. Wang, T. Jiang and M.-H. Xu, *J. Am. Chem. Soc.*, 2013, **135**, 971; (d) C. Jiang, Y. Lu and T. Hayashi, *Angew. Chem., Int. Ed.*, 2014, **53**, 9936; (e) H. B. Hepburn and H. W. Lam, *Angew. Chem., Int. Ed.*, 2014, **53**, 11605; (f) X. Yin, Y. Zheng, X. Feng, K. Jiang, X.-Z. Wei, N. Gao and Y.-C. Chen, *Angew. Chem., Int. Ed.*, 2014, **53**, 6245; (g) G. Yang and W. Zhang, *Angew. Chem., Int. Ed.*, 2013, **52**, 7540; (h) R.-R. Liu, D.-J. Wang, L. Wu, B. Xiang, G.-Q. Zhang, J.-R. Gao and Y.-X. Jia, *ACS Catal.*, 2015, **5**, 6524.

12 The absolute configuration of **3aa** was determined to be (2*S*,8*S*) based on single crystal X-ray analysis. CCDC 1495550 (**3aa**) contains the supplementary crystallographic data for this paper.

13 A. Armstrong and D. P. G. Emmerson, *Org. Lett.*, 2009, **11**, 1547.
