Family-level stereoselective synthesis and biological evaluation of pyrrolomorpholine spiroketal natural product antioxidants†

Alyssa L. Veranoa and Derek S. Tan*ab

The pyranose spiroketal natural products pollenopyrroside A and shensongine A (also known as xylapyrroside A, ent-capparisine B) have been synthesized by stereoselective spirocyclizations of a common C1-functionalized glycal precursor. In conjunction with our previously reported syntheses of the corresponding furanose isomers, this provides a versatile family-level synthesis of the pyrrolomorpholine spiroketal natural products and analogues. In rat mesangial cells, hyperglycemia-induced production of reactive oxygen species, which is implicated in diabetic nephropathy, was inhibited by pollenopyrroside A and shensongine A with mid-μM IC50 values, while unnatural C2-hydroxy analogues exhibited more potent, sub-μM activity.

Introduction

Pyrrolomorpholine spirokets are a novel family of natural products that include both pyranose and furanose isomeric forms and both epimeric configurations at the anomeric carbon (Fig. 1). In 2010, three groups contemporaneously isolated acortatarins A (3) and B (6) from the rhizome of Acorus tatarinowii, pollenopyrrosides A (1) and B (3) from the bee-collected pollen of Brassica campestris, and capparisines A (3) and B (ent-2) from the mature fruit of Capparis spinosa. Acortatarin A and a pyranose isomer named acortatarin C (stereochemistry not assigned) were also isolated as bitter components of whole wheat bread crust.

More recently, the epimeric β-spirokets shensongine A (2) and shensongine B (5) were isolated from capsules of the antiarrhythmic Chinese herbal medicine Shensong Yangxin, along with shensongine C (4), a C2-hydroxy congener of acortatarin A, and pollenopyrroside B (3). Contemporaneously, the same β-spirokets xylapyrrosides A (2) and B (5), were isolated from the fungus Xylaria nigripes.

The plant-derived sources of these natural products have been used in traditional Chinese medicines for the treatment of a variety of diseases. Notably, acortatarins A and B exhibit antioxidant activity in a diabetic renal cell model, inhibiting production of reactive oxygen species (ROS) and significantly attenuating hyperglycemia-induced activation of NADPH oxidase and extracellular matrix production, hallmarks of diabetic nephropathy. The xylapyrrosides also have moderate antioxidant effects and inhibit tert-butyl hydroperoxide-induced cytotoxicity in rat vascular smooth muscle cells. Importantly, oxidative stress has been shown to play a critical role in the Fig. 1 Pyrrolomorpholine spiroketal family of natural products. Structures reflect certain stereochemical revisions made subsequent to the initial isolation reports. Identical structures isolated from different natural sources and given different names (parentheses) are referred to herein by the first published name.
pathogenesis of a wide variety of disease states,² due to the ability of excess ROS to inflict direct damage to essential macromolecules, as well as to lead to aberrant cell signaling.¹⁰,¹¹ Accordingly, these natural products are of interest based on their therapeutic potential to treat diabetic nephropathy, cardiovascular diseases, and other pathologies in which oxidative stress is implicated.³ However, due to the limited quantities available from the natural sources,⁴ efficient synthetic access is required for in-depth biological and structure–activity relationship (SAR) studies. As a result, this family of natural products has attracted considerable attention from the synthetic community.⁷,¹³ We have previously reported concise, highly stereoselective syntheses of the furanose spiroketals acortatarins A (3) and B (6) and shensongine C (4) using stereoselective spirocyclizations of glycal precursors.¹⁴ Herein, we report expansion of this modular approach to a family-level synthesis, providing the naturally-occurring pyranose spiroketal pollenpyrrroside A (1) and shensongine A (2, xylypyrrroside A, ent-capparisine B), as well as corresponding C2-hydroxy analogues, and evaluation of the in vitro antioxidant activity of these compounds.

Results and discussion

Retrosynthetic analysis of pyrrolomorpholine spiroketal natural products

The isomeric nature of the pyrrolomorpholine spiroketal natural products presents an attractive opportunity to develop a family-level synthesis that would provide access to both furanose and pyranose congeners, as well as both anomic stereoisomers.¹⁵ Our laboratory has a long-standing interest in the stereocontrolled synthesis of spiroketals from glycals, with a particular focus on natural product scaffolds for use in probe and drug discovery.¹⁶ Analogous to our approach to the furanose acortatarins,¹⁴ we envisioned that syntheses of the corresponding pyranose isomers could be achieved by stereocontrolled spirocyclization of a pyranoglycal intermediate 7 (Fig. 2). Retrosynthetically, this glycal intermediate 7 would originate from coupling of pyrrole-2,5-dicarboxaldehyde (8) with pyranoarabinal (pyranoribal) derivative 9, both of which can be accessed from commercially-available starting materials (10, 11).

Synthesis of shensongine A via acid-catalyzed spirocyclization of pyranoarabinal intermediate 16

Thus, we synthesized pyrrole-2,5-dicarboxaldehyde (8) as previously reported.¹⁴ To access the pyranoglycal coupling partner 14, commercially available 3,4-di-O-acetyl-D-arabinal (11) was deacetylated¹⁷ then silylated¹⁸ to provide trisopropylsilyl-protected glycal 12 (Fig. 3). This protecting group change was necessary for compatibility with downstream C1-lithiation and also facilitated silica gel purification of intermediates. C1-Formylation¹⁹ of glycal 12 followed by aldehyde reduction provided protected C1-hydroxymethyl arabinal 13. By analogy to our use of the corresponding furanose C1-iodomethyl glycal in our synthesis of the acortatarins,¹⁴ we proceeded with iodination of 13 to give the pyranose C1-iodomethyl glycal 14a. However, attempted coupling of the iodide 14a with pyrrole 8 under basic conditions led to poor yields of pyrrolomethylglycal 15, due to the susceptibility of the C1-iodomethyl arabinal 14a to decomposition. This is in contrast to the observed stability of the corresponding furanose C1-iodomethyl glycal in our acortatarin syntheses.¹⁴ However, we were able to achieve efficient coupling by instead using the more stable mesylate 14b, which provided the desired coupling product 15 in 71% yield. Aqueous base was required for this N-alkylation due to the tendency of pyrrole monomers to dimerize in

\]
monooaqueous conditions.\textsuperscript{20} Monoreduction of the dialdehyde\textsuperscript{21} with NaBH\textsubscript{4} gave the pivotal spirocyclization precursor 16, from which pollenopyrroside A and shensongine A would be accessed. Careful monitoring of the reaction allowed for minimal over-reduction and minimal remaining starting material.

Treatment of arabinal 16 with catalytic Brønsted acids led to exclusive formation of the thermodynamic \( \beta \)-spiroketal 17 (Fig. 4). Desilylation furnished shensongine A (2, xylapyrroside A, ent-capparisine B), whose optical rotation, NMR, and high-resolution mass spectral data matched those reported for the natural products.

Attempted synthesis of pollenopyrroside A via mercury-mediated spirocyclization of arabinal intermediates 16 and 18

In contrast, stereoselective access to the \( \alpha \)-anomer, pollenopyrroside A, proved to be more challenging due to the inherent thermodynamic preferences of this [6,6]-spiroketal system. Formation of the contrathermodynamic \( \alpha \)-anomer was overwhelmingly disfavored under numerous spirocyclization conditions evaluated.\textsuperscript{22} By analogy to our previous work in the corresponding furanoribal-derived [6,5]-spiroketal system,\textsuperscript{14} we first attempted Hg-mediated spirocyclization of pyranoarabinal 16, expecting preferential anti-mercuration to form \( \beta \)-mercurinium intermediate 19, followed by stereoinvertive cyclization to form an \( \alpha \)-spiroketal intermediate (not shown), which could be reduced to the desired \( \alpha \)-spiroketal 23 (Fig. 5). However, under these conditions, we instead observed exclusive formation of the \( \beta \)-spiroketal 17. We attributed this undesired selectivity to steric conflicts between the bulky 3- and/or 4-O-TIPS groups and the morpholine ring en route to the \( \alpha \)-anomer 23. In addition, the 3-O-TIPS protecting group would preclude an intramolecular hydrogen bond with the morpholine oxygen suggested by the crystal structure of pollenopyrroside A,\textsuperscript{2} which may stabilize the \( \alpha \)-configuration. To avoid these issues, we attempted Hg-mediated spirocyclization with the fully deprotected glycal substrate 18. However, the undesired \( \beta \)-anomer 2 was again formed exclusively. We attributed this undesired stereoselectivity to syn-mercuration directed by the free C3-hydroxyl group to form the corresponding \( \alpha \)-mercurinium intermediate 21, followed by stereoinvertive cyclization to \( \beta \)-spiroketal intermediate 22a. Isolation and NMR analysis of the intermediate 2-mercurial spiroketals as the corresponding chlorides \( 20b \) and \( 22b \) provided stereochemical assignments consistent with these mechanistic interpretations.\textsuperscript{23} Use of other mercury salts and less-hindered protecting groups, including a conformationally restricted cyclic carbonate, did not improve stereoselectivity (Table S1†).

Synthesis of pollenopyrroside A via metal-catalyzed spirocyclization of arabinal intermediate 18

Based on the intramolecular hydrogen bond between the 3-hydroxyl group and morpholine oxygen postulated from the crystal structure of pollenopyrroside A,\textsuperscript{2} we next pursued a chelation-based approach to favor formation of the desired \( \alpha \)-spiroketal (Table 1). Such metal-chelation approaches have been used previously to access contrathermodynamic spiroketals.\textsuperscript{24} Treatment of \( \beta \)-spiroketal 2 with various metal salts at reflux in CH\textsubscript{3}CN or dioxane over 24 h had no effect upon the \( \alpha : \beta \) ratio (Table S2†).\textsuperscript{22} Treatment of the glycal
Metal chelation-based spirocyclization approaches to pollenopyrroside A

a Determined by ¹H-NMR. b n.r. = no reaction. c Decomp. = decomposition of starting material. d 25% isolated yield of α-spiroketal. e 1.0 equiv. DTBMP. f 0.5 equiv. TfOH; DTBMP = 2,6-di-tert-butyl-4-methylpyridine.

To assess the mechanistic basis for the observed selectivity in this substrate system, we carried out a control experiment with DTBMP (2,6-di-tert-butyl-4-methylpyridine) as an acid scavenger, but no reaction occurred (entry 5), suggesting that the catalyst might, indeed, be serving as a triflic acid source. However, when the reaction was carried out with TfOH alone, we observed complete diastereoselectivity for the undesired β-spiroketal (2) (entry 6).

Moreover, no reaction was observed upon treatment with ScCl₃ alone (entry 7). In contrast, treatment of glycal 18 with both ScCl₃ and TfOH together (entry 8) recapitulated the 60 : 40 ratio of diastereomeric spirotetal products, favoring the desired α-anomer 1 (entry 4). We have recently used Sc(OTf)₃ in stereoselective spirocyclizations of exo-glycal epoxides to form benzannulated spirotetals. In those reactions, solvents played a dramatic role, with the catalyst acting as a Lewis acid in THF but as a mild source of triflic acid in CH₂Cl₂. To assess the mechanistic basis for the observed selectivity in this substrate system, we carried out a control experiment with DTBMP (2,6-di-tert-butyl-4-methylpyridine) as an acid scavenger, but no reaction occurred (entry 5), suggesting that the catalyst might, indeed, be serving as a triflic acid source. However, when the reaction was carried out with TfOH alone, we observed complete diastereoselectivity for the undesired β-spirotetal (2) (entry 6).

Moreover, no reaction was observed upon treatment with ScCl₃ alone (entry 7). In contrast, treatment of glycal 18 with both ScCl₃ and TfOH together (entry 8) recapitulated the 60 : 40 ratio of diastereomeric spirotetal products, favoring the desired α-anomer 1 (entry 4). Notably, combination of MgCl₂ or ZnCl₂ with TfOH also afforded a 50 : 50 mixture of the two diastereomeric spirotetales and β-spirotetal 2. This is in contrast to our previous study with exo-glycal epoxides, in which Sc(OTf)₃ served as either a Lewis acid or a Bronsted acid source exclusively, depending upon solvent selection. Unfortunately, the diastereomeric mixture was difficult to separate, resulting in only a 25% isolated yield of pollenopyrroside A (1).

Synthesis of pollenopyrroside A via methanol-catalyzed kinetic spirocyclization of arabinoidal intermediate 16

Thus, to provide more stereoselective access to pollenopyrroside A (1), we turned to our previously reported methanol-catalyzed kinetic spirocyclization of glycal epoxides. While we recognized that this approach would introduce the need for deoxygenation of the resulting 2-hydroxyl group, this was balanced by the much higher stereoselectivity expected with this spirocyclization. In addition, this epoxidation–spirocyclization strategy would provide access to the non-natural 2-hydroxyfuranose analogues for biological evaluation, complementing the known 2-hydroxy natural products in the furanose series. Accordingly, anti-epoxidation of glycal 16 with DMDO was followed by spirocyclization with inversion of configuration in methanol to give the desired α-spirotetal 24 in >98 : 2 dr (Fig. 6a). Desilylation of 24 provided a 2-hydroxy analogue of pollenopyrroside A, 25, for biological evaluation below. Alternatively, Barton–McCombie deoxygenation of 24 at the 2-position and desilylation provided pollenopyrroside A (1) in 46% yield over four steps from glycal precursor 16.

For completeness, we also carried out a stereo-complementary spirocyclization of the glycal epoxide derived from 16 using our previously established Ti(O-iPr)₄-catalyzed kinetic spirocyclization with retention of configuration to provide the corresponding β-spirotetal 27 with complete β-diastereoselectivity (Fig. 6b).

Acid equilibration studies of natural products 1 and 2 and 2-hydroxy analogues 25 and 28

Acid equilibration experiments under aqueous conditions showed that pollenopyrroside A (1) was kinetically stable at pH ≥ 5, but underwent complete conversion to its C1-epimer shensongine A (2) at pH ≤ 4. Conversely, shensongine A was stable down to pH 1, indicating that this β-spirotetal is thermodynamically favored (Fig. 6c). In the 2-hydroxyfuranose series, both 25 and its C1-epimer 28 were kinetically stable down to pH 1. Accordingly, epimerization would not be expected for any of these compounds in biological assays under physiologic conditions at pH 7.4.

Evaluation of antioxidant activity of pyrrolomorpholine spirotetales

Previous reports have demonstrated the antioxidant activity of acortatarin A against high glucose-induced oxidative stress in rat mesangial cells suggesting that this scaffold may have therapeutic potential for the treatment of diabetic nephropathy. Thus, we evaluated the antioxidant activity of the complete α-enantiomeric family of furanose and pyranose pyrrolomorpholine spirotetals natural products and analogues. Intracellular ROS levels were measured using the cell-permeable 2′,7′-dichlorofluorescein diacetate (DCFH-DA), which is converted to the highly fluorescent 2′,7′-dichlorofluorescein (DCF)
Fig. 6 (a) Synthesis of pollenopyrroside A via MeOH-catalyzed kinetic spirocyclization followed by 2-deoxygenation. (b) Synthesis of 2-hydroxy analogue of shensongine A via Ti(O-iPr)4-mediated kinetic cyclization. (c) Acid equilibration experiments indicate that β-spiroketal shensongine A (2) is thermodynamically favored over α-epimer pollenopyrroside A (1) in aqueous acid (pD ≤ 4) while 2-hydroxy analogues 25 and 28 do not equilibrate down to pD 1. DMDO = dimethyldioxirane; AIBN = azobisisobutyronitrile.

*Rat mesangial cells are highly sensitive to hyperglycemic conditions, and a significant increase in ROS was observed after 3 h exposure to 30 mM d-glucose.

Consistent with the previous report,1 acortatarins A (3) and B (6) reduced high glucose-induced ROS generation in a dose-dependent manner, with IC50 values of 4.6 and 11 μM, respectively, returning ROS levels to that of normal glucose conditions (Table 2, entries 2, 5). Compared to acortatarin A (3), the β-spiroketal shensongine B (5) was 4-fold less potent (entries 2, 3), suggesting that the spiroketal stereocenter may be important for activity. Consistent with this trend, the α-spiroketal shensongine C (4) was also more potent than its β-spiroketal congenor acortatarin B (6) (entries 4, 5).

In conclusion, we have developed an efficient, stereoselective, family-level synthesis of the pyrrolomorpholine spiroketal natural products, providing access to pollenopyrroside A (1) and shensongine A (2), as well as the corresponding 2-hydroxy analogues (25, 28), from the common pyranobarabinal intermediate 16. Pollenopyrroside A was synthesized in 11 steps and 13% overall yield from 3,4-di-O-acetyl-n-arabinal, and shensongine A was accessed in 9 steps and 28% overall yield. Complete diastereoselectivity was achieved for the key
spiroketal-forming steps toward both natural products, as well as the 2-hydroxy congeners. This compares favorably to previous syntheses, and provides practical access to the natural products and a variety of analogues. Indeed, while the synthesis of pollenopyrroside A involved an epoxidation-cyclization strategy that required subsequent C2-deoxygenation to afford the natural product, this route also provided convenient access to the corresponding 2-hydroxy analogues, which have not yet been described in the pyranose series but are known as natural products in the isomeric furanose series (i.e.: 4, 6). Evaluation of antioxidant activity against hyperglycemia-induced ROS in rat mesangial cells indicated similar activities for the anomeric antioxidant activity against hyperglycemia-induced ROS in rat ongoing and will be reported in due course.

The pyranose series (4), and led to the discovery of novel 2-hydroxy analogues considerably more potent than the natural product, this route also provided convenient access to the corresponding 2-hydroxy analogues, which have not yet been described in the pyranose series but are known as natural products in the isomeric furanose series (i.e.: 4, 6). Evaluation of antioxidant activity against hyperglycemia-induced ROS in rat mesangial cells indicated similar activities for the anomeric natural products pollenopyrroside A (1) and shensongine A (2). Strikingly, the 2-hydroxy analogues 25 and 28 exhibited 30- to 40-fold lower IC₅₀ values compared to the natural products, albeit with incomplete ROS inhibition due to U-shaped dose response curves. Notably, in the furanose series, the α-spiroketalts acortatarin A (3) and shensongine C (4) were considerably more potent than the β-anomers, shensongine B (5) and acortatarin B (6), although this trend did not extend to the pyranose series (cf. 1, 2). Overall, this family-level synthesis allowed the first direct comparison of the antioxidant activities of the entire β-enantiomeric series of furanose and pyranose isomers, and led to the discovery of novel 2-hydroxy analogues with potent, sub-μM IC₅₀ values. These more potent analogues may be useful for mechanistic studies, including target identification efforts. Further investigation into the mechanisms of action of these compounds and additional analogues are ongoing and will be reported in due course.
