# Ground-state dioxygen undergoes metal-free [3 + 2]-annulations with allenes and nitrosoarenes under ambient conditions†

Jinxian Liu,‡<sup>ab</sup> Manisha Skaria,‡<sup>a</sup> Pankaj Sharma,<sup>a</sup> Yun-Wei Chiang <sup>a</sup> and Rai-Shung Liu <sup>a</sup>

The cycloadditions of molecular dioxygen with neutral  $\pi$ -bond motifs rely heavily on singlet-state  $^{1}O_{2}$ , whereas ground state  $^{3}O_{2}$  is chemically inactive. Here we report novel [3 + 2]-annulations among ground-state  $^{3}O_{2}$  (1 bar), allenes, and nitrosoarenes at low temperatures, efficiently yielding dioxygen-containing oxacycles. With less hindered 1-arylallene derivatives, these dioxygen species undergo skeletal rearrangement to 3-hydroxy-1-ketonyl-2-imine oxides. These cycloadditions represent valuable one-pot O,N,O-trifunctionalizations of allenes. Our EPR experiments confirm the presence of 1,4-diradical intermediates from an allene/nitrosoarene mixture, which manifest the hidden diradical properties of nitrosoarenes.

#### Introduction

Cycloadditions of two or three  $\pi$ -bond molecules are powerful tools to access carbo- or heterocycles. Ground-state  $^3O_2$  has low-lying LUMO orbitals, but its triplet state greatly reduces its chemical reactivity toward neutral molecules¹ unless a metal catalyst is present. The cycloadditions of  $^3O_2$  dioxygen rely nearly exclusively on prior photo-activation to form singlet-state  $^1O_2$  (ref. 1) that reacts with dienes,² olefins³ or even arenes⁴ in [n+2]-cycloadditions (n=2 and 4, Scheme 1, eqn (1)). This photolytic process requires a sensitizer in a cold bath (-40 °C) over a protracted period (>12 h) because highly energetic  $^1O_2$  might produce byproducts from the oxygen-ene reactions⁵ and oxidative C=C cleavages.⁶ In the case of allenes, singlet dioxygen afforded a complicated mixture of undesired compounds. $^{7a,b}$ 

As ground-state  $^3O_2$  is a free  $\pi$ -molecule and is available everywhere; its metal-free [n+2]-cycloadditions with commonly used unsaturated hydrocarbons would provide a clean and cheap synthesis of valuable 1,n-diols, although there is no literature precedence. As far as we are aware, only 1,4-diradical precursors such as o-benzocyclobutanes, $^8$  1,2,6,7-octate-traenes, $^9$  2,3-dimethylenebicyclo[2.2.0]hexane $^{10}$  and other 1,4-diazo species $^{11}$  reacted with ground-state  $^3O_2$  in thermal [4 + 2]-

Scheme 1 Cycloadditions of unsaturated hydrocarbons with  ${}^{1}O_{2}$  and  ${}^{3}O_{2}$ .

cycloadditions; these precursors are too uncommon to show general utility. We recently achieved metal-catalyzed annulations of N-hydroxy allenylamines with nitrosoarenes via a single radical process.<sup>7d</sup> In search of a breakthrough in dioxygen chemistry, we developed facile [3 + 2]-cycloadditions among nitrosoarenes, allenes and ground-state <sup>3</sup>O<sub>2</sub> to efficiently afford N-(1,2-dioxolan-4-ylidene)aniline oxides (eqn (2)). Particularly notable are the ambient conditions: -15 to 0 °C, <sup>3</sup>O<sub>2</sub> (1 bar), no light, no catalyst and no additive. Importantly, these facile spinforbidden dioxygen annulations reveal a new role of nitrosoarenes as effective diradical precursors that is synthetically significant in nitroso chemistry.12 In the context of nitroso/ alkene and nitroso/alkyne reactions, 13 theoretical calculations by Houk<sup>12e,f</sup> suggested the intermediacy of the diradical species, but these transient species could not be trapped with dioxygen or other small molecules.

Reported O,N,O-trifunctionalizations

Fig. 1 *O,N,O*-Trifunctionalizations of allenes and selected natural products.

2-Amino-1,3-diols are present in numerous natural products with diverse biological activity (Fig. 1). <sup>14</sup> Catalytic O,N,O-trifunctionalization of allenes is a new appealing tool to assess these motifs, as noted by the work of Schomaker, who reported Rh-catalyzed intramolecular cyclizations of homoallenylsulfamate esters via a two-step sequence. <sup>15 $\alpha$ </sup> In contrast, our one-pot intermolecular O,N,O-functionalizations employ common and cheap nitrosoarenes, allenes and oxygen.

#### Results and discussion

Table 1 presents the optimized yields of a O,N,O-trifunctionalized molecule  $\bf 3a$  from a mixture of allene  $\bf 1a$ , nitrosobenzene  $\bf 2a$  (n equiv.) and  $O_2$  (1 bar). When 1.5 equiv. of nitrosobenzene  $\bf 2a$  was used in cold THF ( $-15\,^{\circ}$ C), the yield was 43% (entry 1). The yield of  $\bf 3a$  increased to 63% with nitrosobenzene in three fold proportions (entry 2). In other solvents, the yields of  $\bf 3a$  were 50% in toluene, 54% in CH<sub>3</sub>CN, and 58% in DCM (entries 3–5). The yield of  $\bf 3a$  decreased substantially to 10% in THF at 25  $^{\circ}$ C (entry 6). The reaction under  $N_2$  failed to yield the desired product  $\bf 3a$  in a traceable amount (entry 7). $^{16}$  Compound  $\bf 3a$  assumes an Econfiguration with its hydroxyl cis to the nitrone oxygen to form a hydrogen bond. This structure was inferred from X-ray diffraction measurements of its relative  $\bf 3b^{17}$  (Table 2 entry 1).

 $^a$  [1a] = 0.1 M.  $^b$  Product yields are reported after purification using a silica column.

**Table 2** O,N,O-Trifunctionalizations of allenes with  $O_2$  and  $ArNO^{a,b}$ 

 $^a$  [1] = 0.1 M.  $^b$  Product yields are reported after purification using a silica column.

To assess the reaction scope, we applied these optimized conditions to additional mono- and 1,3-disubstituted allenes **1b-1g**; Table 2 summarizes the results. For phenylallene **1a**, its corresponding reactions with 4-methyl-, 4-methoxy- and 3,5-dimethylphenylnitroso species afforded 3-hydroxy-1-ketonyl-2-imine oxides **3b-3d** in 54–68% yields (entries 1–3). Varied arylallenes **1b-1e** (Ar = 4-MeC<sub>6</sub>H<sub>4</sub>, 4-ClC<sub>6</sub>H<sub>4</sub>, 4-BrC<sub>6</sub>H<sub>4</sub> and 3-thienyl) yielded desired compounds **3e-3h** in satisfactory yields (50–74%, entries 4–6). 3-Substituted phenylallenes **1f** and **1g** (R = n-Bu and R =

Notably, the reaction of sterically hindered 3-cyclohexyl-1-phenylallene 1i with 4-methoxyphenylnitroso 2c and  $O_2$  (1 bar) afforded dioxygen-containing oxacycle 4a together with desired product 3l; the yields were 45% and 28%, respectively. Species 4a assumes an anti-configuration (dr > 20 : 1) according to its  $^1$ H NOE spectra; this new compound was efficiently converted to compound 3l in hot THF (eqn (3)), via a Kornblum-DeLaMare rearrangement.  $^{22}$ 

The kinetic stability of dioxygen-containing oxacycle **4a** is enhanced with a suitable steric environment. We further tested the reactions on various 1-aryl-1-methylallenes **1j–1m** with 4-methoxyphenylnitroso **2c** and  $O_2$  (1 bar) in THF (0 °C), generating dioxygen-containing compounds **4b–4e** (Ar = 4-RC<sub>6</sub>H<sub>4</sub>, R = H, Me, MeO, Br) in satisfactory yields (Table 3, entries 1–4). The molecular structure of compound **4b** was confirmed by its X-ray

Table 3 [3 + 2]-Cycloadditions among  $O_2$ , allenes and nitrosoarenes  $^{a,b}$

diffraction pattern.<sup>17</sup> Various 1-aryl-3,3-dimethylallenes 1n-1q (Ar = 4-RC<sub>6</sub>H<sub>4</sub>, R = H, Me, MeO, Br), electron-rich nitrosoarenes and O<sub>2</sub> were also amenable to such cycloadditions, yielding desired compounds 4f-4m in satisfactory yields (60–72%, entries 5–12) except 4k in only 38% yield. This dioxygen cycloaddition was applicable to cyclohexylidene-derived phenylallene 1r, affording compound 4n in 66% yield (entry 13). Compounds 4 serve as the first examples of the cycloadditions of ground-state  $^3O_2$  with unsaturated hydrocarbons at low temperatures.

An electron-deficient nitrosoarene is an inapplicable substrate, as shown by eqn (4). Under  $O_2$ , the reaction of trisubstituted allene  $\mathbf{1p}$  with 4-chlorophenylnitroso species  $\mathbf{2f}$  in cold THF (0 °C) afforded nitroso-containing cycloadduct  $\mathbf{5a}$  in 53% yield; the dioxygen-containing product,  $\mathbf{ca}$ . 5%, was unstable for isolation (eqn (4)). In contrast, the same allene  $\mathbf{1p}$  could deliver dioxygen-containing species  $\mathbf{4j}$  and  $\mathbf{4k}$  using electron-rich nitrosoarenes under the same conditions (entries 9–10, Table 3).

Table 4 [3 + 2]-Cycloadditions among allenes and nitrosoarenes under  ${\rm N_2}^{a,b}$ 

 $^{a}$  [1] = 0.1 M.  $^{b}$  Product yields are reported after purification using a silica column.

Under nitrogen, trisubstituted allene **1p** reacted with 4-methylphenylnitroso **2b** in cold THF to form nitroso-containing cycloadduct **5b** in 60% yield (eqn (5)). The stereochemistry and its E-configuration of this new compound was confirmed by its X-ray diffraction pattern.<sup>17</sup> Such a new reaction represents a new and useful *O,N,N*-functionalization of allenes. A preliminary survey of the reaction scope is summarized in Table 4. We tested the reactions on **1,3**-di- and **1,1,3**-trisubstituted allenes **1g** and **1t** that reacted with nitroso-arenes (R = H, Cl, CO<sub>2</sub>Et) to afford nitroso-containing cycloadducts **5c**–**5g** in reasonable yields (58–83%). Furthermore, the anti-configuration of compound **5c** was determined by X-ray diffraction.<sup>17</sup>

Dioxygen-containing heterocycles 4 are readily reduced with Pd/C,  $H_2$  (1 atm) in MeOH (23 °C)<sup>18</sup> to cleave their O–O bonds, satisfactorily yielding desired 1,3-dihydroxy-2-imine oxides 6. These reductions highlight the utility of molecular oxygen to afford 1,3-dihydroxy-2-amino derivatives. Several instances of affording tertiary 1,3-alcohol derivatives are illustrated in eqn (6) and (7); their chemical yields exceed 65%. Under these reductions, the valuable nitrone functionalities of these acyclic 1,3-diols remain intact as indicated by their HRMS and  $^{13}$ C-NMR spectra.

**Edge Article** 

The facile cycloadditions among allenes, nitrones and ground-state O2 are very astonishing because an intersystem crossing (ISC) must be involved for one key intermediate. To investigate the mechanism, we examined the reaction of 1phenyl-3-cyclopropylallene 1s with 4-methylphenylnitroso species 2b under O2, yielding compound 3m in 71% yield; this transformation did not induce cyclopropane cleavage because of the stability of the phenylallylic radical A (eqn (8)). 19 We thus exclude the intermediacy of the dicarbon radical A', although analogous carbon radicals were postulated for the o-quinodimethine species.8 We isolated compound 7 in 13% yield from the reaction of 1-phenylallene 1a with PhNO (1.2 equiv.) and TEMPO (2 equiv.) under N2, indicating the formation of diradical intermediates (eqn (9)). We employed EPR to characterize the diradical species from a mixture of 3,3-dimethyl-1phenylallene 1n and nitrosobenzene 2a in THF at 0 °C (0.5 h). Fig. 2 (top) shows the EPR signal of the diradical species; the intensity of this signal remains unchanged for 5 h under N2. The simulation analysis was performed using the EasySpin program.20 The satisfactory fit was achieved with a twocomponent simulation (bottom). The abundant component (70%) corresponds to nitrogen-centered diradicals (g = 2.00616,  $a_{\rm N} = 10.7$  G and 3.0 G).<sup>21</sup> The minor component corresponds to a monoradical nitroxide with  $a_N = 10.7$  G. Notably, when recorded at T < 130 K, the spectrum exhibits a well-known nitroxide rigid-limit lineshape in accordance with the above simulation result; the coupling of unpaired electrons with the nitrogen center is evident.

Scheme 2 depicts a plausible mechanism to rationalize the remarkable facility of such dioxygen annulations. We postulate

Scheme 2 A plausible mechanism

that allene 1 reacts initially with nitrosobenzene to form 1,4diradical species A, which is likely to be a major component, as detected in the EPR spectra; its nitroxy and allylic radicals are expected to couple with nitrogen in two magnitudes, i.e.  $a_N =$ 10.7 G and 3.0 G respectively.21 The capture of molecular dioxygen 3O2 by 1,4-diradical species A forms peroxy diradical B in a triplet state, as the two radical centers of species B are remote from each other, rendering an intersystem crossing (ISC) feasible. After a change of spin state, singlet-state diradical B' is expected to form primary 1,2-oxaziridine diradical C through a 3-exo-trig cyclization that is more feasible than an alternative 5-endo-trig cyclization.23 A final radical-radical coupling of resulting species C forms precursor D, and ultimately yields desired 1,2-dioxolanes 4. This proposed path rationalizes the formation of compound 7 from the TEMPO experiment (eqn (9)) well. The trapping of the 1,4-biradical generates single radical species F that undergoes a rapid 3-exotrig cyclization to form benzylic radical G. A second trapping of this species with the TEMPO radical is expected to yield species I that is prone to hydrolysis on a silica column to yield observed product 7.

#### Conclusions

Prior to this work, singlet state oxygen  $^1O_2$  failed to react with allenes to give useful oxygenated products. This study reports the first examples of metal-free [3 + 2]-cycloadditions among allenes, nitrosoarenes and ground-state  $^3O_2$  (1 bar) at low temperatures, efficiently yielding dioxygen-containing oxacycles. With less hindered 1-arylallene derivatives, the resulting oxacycles undergo skeletal rearrangement to 3-hydroxy-1-ketonyl-2-imine oxides. These transformations highlight a cheap, efficient and clean synthesis of 1,3-dihydroxy-2-amino derivatives. Our experimental data indicate that an initial attack of a nitrosoarene at an allene generates a diradical species that is detectable with EPR. We envisage that the concept of nitrosoarenes as diradical precursors will inspire new synthetic concepts.

- 19 The rearrangement of cyclopropylmethyl radicals to homoallylic radicals is seriously affected by the radical substituents; this process is reversible. Previous studies by Bowry indicate that stable cyclopropylbenzylic radicals are reluctant to form the corresponding homoallylic radicals. In our system, key intermediate **A** is a very stable phenylallylic radical that has many resonance forms. The equilibrium of this rearrangement is expected to be favourable for initial radicals **A** that can be trapped by O<sub>2</sub> to yield the observed product **3m**. For the nature of this radical rearrangement, see the leading reference, A. J. Beckwith and V. W. Bowry, *J. Am. Chem. Soc.*, 1994, **116**, 2710–2716.
