This correction note acknowledges that the withdrawal of four articles<sup>1–4</sup> has affected some statements made in ref. 5. Specifically, in the last paragraph of Section IV of ref. 5, the results of ref. 2 were applied to make an incorrect statement that there should be a chain stretching contribution to the macroscopic stress even for rates lower than the Rouse rate (*i.e.*,  $Wi_R \ll 1$ ). The paragraph continued by repeating the erroneous conclusions from ref. 2 that (a) the shear stress overshoot originates from retraction of stretched chains on time scales longer than the Rouse time and (b) such a molecular dynamics simulation result does not support the tube model's premise that chain retraction occurs inside a tube on Rouse time.

To dispel any plausible confusion in the literature, we make a short comment. Although the contour length may be at its equilibrium value on the tube segment scale either during startup shear with  $Wi_R < 1$  or after relaxation for a period as long as the Rouse time from fast ( $Wi_R \gg 1$ ) step strain, there is no reason that the stress can still be calculated based on tube segmental orientation. The molecular mechanism for stress overshoot during startup shear with  $Wi_R < 1$  remains an open question.

The Royal Society of Chemistry apologises for these errors and any consequent inconvenience to authors and readers.
