Spin-dimer networks: engineering tools to adjust the magnetic interactions in biradicals†

Yulia B. Borozdina,^{ab} Evgeny A. Mostovich,^{ac} Pham Thanh Cong,^d Lars Postulka,^d
Bernd Wolf,^d Michael Lang^d and Martin Baumgarten^{id}*^a

Magneto-structural correlations in stable organic biradicals have been studied on the example of weakly exchange coupled models with nitronyl nitroxide and imino nitroxide spin-carrying entities. Here, heteroatom substituted 2,2'-diaza- and 3,3'-diaza-tolane bridged biradicals were compared with the hydrocarbon analogue, while a biphenyl model with its 2,2'-bipyridine counterpart. For a 3,3'-diazatolane bridge the torsional angle between the nitronyl nitroxides and the pyridyl rings increased heavily (~52–54°) leading to a smaller theoretical intra-dimer exchange coupling value. However, a very large anti-ferromagnetic coupling was obtained experimentally. This could be appropriately explained by the presence of dominating inter-dimer exchange between the molecules. For the bis(imino nitroxide) with tolane bridge a field induced ordered state between 1.8 to 4.3 T in AC-susceptibility measurements was observed. In terms of a Bose Einstein condensate (BEC) of triplons this phenomenon could be described as a magnetic field induced ordered phase with 3D character.

Introduction

Magnetic dimers formed by weakly interacting antiferromagnetically coupled spin $S = 1/2$ centres are recognized as suitable candidates for exploring critical phenomena under well-controlled conditions.¹ When these systems are placed in a magnetic field strong enough to close the dimer gap, a gas of triplet excitations (triplons) is formed.¹ Depending on the topology of the dimer-dimer couplings, various scenarios can be observed. Prominent examples include the Bose-Einstein condensation (BEC) of triplons in three-dimensionally-coupled dimer systems, as described by Tchernyshyov *et al.*,² and the Luttinger-liquid behavior revealed in a one-dimensional spin-ladder system by Krämer and co-workers.³ More recently, a Berezinskii–Kosterlitz–Thouless scenario was observed by Tutsch *et al.* in a two-dimensional coordinated copper polymer with large interlayer spacing.⁴

In general, organic magnetic materials possess properties not shown by traditional inorganic compounds.^{5–8} Plasticity, flexibility and solubility in common organic solvents define the ease of various device fabrication. Advanced chemistry techniques permit small structural modifications in already achieved model systems in order to fine-tune their physical properties. In addition, organic-based magnetic materials offer a number of convenient tools extremely helpful in controlling the intra- and inter-dimer exchange coupling, such as π – π interactions, hydrogen bonding, *etc.* Nitronyl nitroxide (NN) radicals are well-known for their stability and bidentate character.^{9,10} NN radicals are among the most popular spin carriers used to construct molecule-based magnets.¹⁰

Importantly, in these radicals the spin density of the unpaired electron is delocalized over two semi-equivalent sites of coordination. This in turn allows the arrangement of the NN-molecules into a supramolecular network of interacting spins.¹¹ Theoretical studies emphasized the importance of the mutual orientation and the relative distances in the crystal packing for promoting an efficient magnetic coupling.^{11,12} As was mentioned by Lahti,¹³ minor changes in the crystal packing of biradicals could result in significant alterations of the magnetic behavior in the bulk material. In this regard the influence of the π -bridges on the intra- and intermolecular exchange interactions in conjugated biradical networks was studied on the example of the diazotolane dinitroxide models (Fig. 1). It was anticipated that heteroatom substitution could offer a particularly effective pathway for transmitting the magnetic interactions.¹⁴

Fig. 1 Structure of biradical model systems 1–5.

Typically, imino nitroxides (INs) reveal a reduced J_{dimer} value when compared to the corresponding NN biradicals. Taking this fact into consideration, already known bridges could be used, where otherwise a strong intramolecular exchange coupling was observed.¹¹ Following this strategy, three bisimino nitroxides **3d**, **4d**, **5d** were prepared (Fig. 1).¹⁵

In the current work we report the synthesis of a series of new nitroxide biradicals (Fig. 1), their characterization, including X-ray structural analysis and their magnetic properties, which are discussed with respect to the quantum chemical calculations based on the DFT approach.

Results and discussion

Synthesis of nitroxide biradicals

Access to the family of diazatolane biradicals **1c** and **2c** required the synthesis of key precursors **1a** and **2a**, which were prepared following Sonogashira–Hagihara methodology.¹⁶ Interestingly, both structural isomers **1a** and **2a** could be achieved starting from the same precursor, *i.e.* commercially available 2,5-dibromopyridine **6** (Scheme 1). Depending on the reaction conditions (such as solvent, base) compound **6** could be selectively monolithiated.^{17–21} More precisely, reaction times and solvents played a crucial role in the course of electrophilic substitution, leading to predominant formation of the organolithium intermediate at the 2 or 5 position.^{22,23} In order to drive the reaction in the course of kinetically more favorable 2-bromo-5-carbaldehyde-pyridine **7**, it was carried out in dry diethyl ether at $-78\text{ }^{\circ}\text{C}$, and DMF was added to the mixture 20 min after the addition of *n*-BuLi was complete (Scheme 1).

According to the preliminary results obtained by our group, 2-ethynyl-5-formyl-pyridine was unstable. Therefore, at first aldehyde **7** was transformed into 2-bromo-5-[1,3]dioxolan-2-yl-pyridine **8** following the standard protocol.²⁴ Compound **8** was involved in Pd-catalyzed Sonogashira–Hagihara coupling with trimethylsilyl acetylene (TMSA) giving rise to derivative **9**. Hydrolysis of the trimethylsilyl group using 1 N NaOH solution in a deaerated THF–water mixture (1 : 1) granted the NMR-pure ethynyl derivative **10**, which was used further without additional purification.

Sonogashira–Hagihara coupling reactions can be successfully carried out under various conditions.¹⁶ For our systems it was found that by decreasing the reaction temperature from $80\text{ }^{\circ}\text{C}$ (DMF/Et₃N, 1 : 1) to $\sim 22\text{ }^{\circ}\text{C}$ (CH₃CN/Et₃N, 1 : 1) the formation

Scheme 1 Synthesis of dialdehydes **1a** and **2a**. Reagents and conditions: (i) (a) *n*-BuLi, Et₂O, $-78\text{ }^{\circ}\text{C}$, under Ar, 45 min, (b) DMF, $-78\text{ }^{\circ}\text{C}$, under Ar, 105 min, (c) HCl (3%), 20 min; (ii) ethyleneglycol, *p*-TsOH, benzene, reflux, 20 h; (iii) TMSA, Pd(PPh₃)₂Cl₂, CuI, PPh₃, DMF, Et₃N, heating at $80\text{ }^{\circ}\text{C}$ under Ar, 14 h; (iv) 1 M NaOH, H₂O–THF, $5\text{ }^{\circ}\text{C}$, 35 min; (v) Pd(PPh₃)₂Cl₂, CuI, PPh₃, CH₃CN, Et₃N, at rt under Ar, 18 h; (vi) *p*-TsOH, H₂O–acetone, 84 h; (vii) (a) *n*-BuLi, toluene, $-78\text{ }^{\circ}\text{C}$, under Ar 2 h, (b) DMF, $-78\text{ }^{\circ}\text{C}$, under Ar, 2 h, (c) NH₄Cl, 30 min; (viii) TMSA, Pd(PPh₃)₂Cl₂, CuI, PPh₃, DMF, Et₃N, heating at $80\text{ }^{\circ}\text{C}$ under Ar, 16 h; (ix) K₂CO₃, MeOH, under Ar 90 min; (x) **11**, Pd(PPh₃)₂Cl₂, CuI, PPh₃, DMF, Et₃N, heating at $80\text{ }^{\circ}\text{C}$ under Ar, 12 h.

of several side-products was prevented. Therefore, the attachment of bromo derivative **8** to the pre-organized ethynyl-pyridine **10** was carried out at room temperature in the CH₃CN/Et₃N solvent mixture, which led to the corresponding product in a reasonable yield (72%). Notably, our attempts to remove dioxolane protective groups in the presence of dilute HCl (3%) resulted in precipitation of the acid by the triple bond. Thus, the final step towards **1a** was performed under milder conditions. To a solution of the dioxolane precursor in an acetone–water mixture (7 : 1) a catalytic amount of *p*-TsOH acid (2 mol%) was added.²⁴ Upon stirring the reaction mixture for 3 days at room temperature the target 2,2′-diazatolane 4,4′-dialdehyde **1a** was obtained in nearly quantitative yield (81%).

The isomeric 3,3′-diazatolane dialdehyde **2a** was obtained in a similar way (Scheme 1). Here, 2,5-dibromo-pyridine **6** was selectively monolithiated in position 2 in toluene media. Time of the exchange reaction with *n*-BuLi was increased to 90 min to ensure the desired organolithium intermediate formation, and precursor **11** was obtained in 49% yield.²¹ Next, standard Sonogashira–Hagihara methodology¹⁶ was employed. Final separation on a silica gel column with a hexane/EtOAc eluent mixture (3 : 2) yielded 5,5′-ethyne-1,2-diylbis(pyridine-2-carbaldehyde) **2a** in decent yield (69%).

Several synthetic procedures towards compound **3a** were reported in the literature.¹⁵ Inspired by the efficiency and simplicity of the approach sketched in Scheme 2, commercially available 4,4′-dibromobiphenyl **14** was treated with *n*-BuLi in the presence of a catalytic amount of TMEDA. After addition of dry DMF, typical work-up and purification, biphenyl dialdehyde **3a** was isolated in 58% yield.

Bipyridine-4,4′-dicarbaldehyde **4a** was achieved upon formation of 5,5′-bis-(bromo-methyl)-2,2′-bipyridine **16** from the corresponding dimethyl-bipyridine precursor **15** following the procedure described by Vögtle.²⁵ Then nucleophilic substitution under Sommelet

Scheme 2 Synthesis of dialdehydes **3a** and **4a**. Reagents and conditions: (i) (a) *n*-BuLi, THF, TMEDA, under Ar, $-78\text{ }^{\circ}\text{C}$ 30 min, $-50\text{ }^{\circ}\text{C}$ 30 min; (b) DMF, $-78\text{ }^{\circ}\text{C}$, under Ar, 1 h, (c) NH_4Cl , 20 min; (ii) NBS, CCl_4 , benzoyl peroxide, reflux under Ar, 14 h; (iii) hexamethylenetetramine, $\text{EtOH-H}_2\text{O}$, reflux, 60 h.

conditions led to **4a**.²⁶ Synthesis of tolane dialdehyde **5a** was described elsewhere.¹¹

Final steps in the synthesis of nitroxides included condensation between 2,3-bis(hydroxyamino)-2,3-dimethylbutane (BSA) with an aldehyde, followed by the oxidation of the condensation products (*i.e.* imidazolidine derivatives **1–5b**).^{11,15} Typically, the first reaction was performed under strictly anaerobic conditions in refluxing toluene (Scheme 3). Here, the corresponding *N,N'*-dihydroxyimidazolidines **1b**, **3b**, **4b**, and **5b** were obtained in quantitative yields. As an exception synthesis of diazotolane imidazolidine **2b** was realized in absolute degassed methanol at room temperature.

In order to avoid further oxidation, and, therefore, to diminish the loss of the radical units, oxidation of *N,N'*-dihydroxyimidazolidine intermediate **1b** with sodium periodate was carried out at $\sim 0\text{--}5\text{ }^{\circ}\text{C}$ using an ice bath.²⁷ The progress of the reaction could be conveniently monitored by TLC analysis of the reaction mixture aliquots. Synthesis of derivative **2c** was achieved using an excess of MnO_2 in methanol. Imino biradicals **1d**, **3d**, and **4d** were obtained following the procedure described by Tretyakov *et al.*^{28,29} This method helped to avoid the harmful usage of acids and to synthesize the target molecules in better yields. As an illustration, transformation of imidazolidine **1b** into the corresponding imino biradical **1d** with an excess of MnO_2 in CH_3NO_2 media is depicted in Scheme 3. To aid the interpretation of magnetic properties of the isomeric NN **1c** and **2c** related IN biradical **1d** was also prepared.

The UV-Vis absorption spectra of **1c** and **2c** with maxima around 600 nm were typical for the nitronyl nitroxides, while the red bisiminonitroxides absorbed around 460 nm (Table S2, ESI[†]). The EPR spectra of bisnitronyl nitroxides exhibited nine lines with $A_n/2$ spacing for four equivalent nitrogens with two

strongly coupled radicals. The bisiminonitroxides (**1d**, **3b**, **4b**, **5d**) featured 13 lines, corresponding to the inequivalent nitrogens of the imidazolidine ring (as presented in the Graphical abstract and Table S2, ESI[†]).

Crystal structure analysis

Crystals were obtained by slow diffusion of hexane in dichloromethane solutions of the nitroxide biradicals at room temperature. Deep-blue needle crystals of nitronyl nitroxides **1c** and **2c** and red blocks of imino nitroxides **1d**, **3d**, **4d**, and **5d** were then characterized using X-ray diffraction analysis. Selected torsion angles are reported in Table 1 (with some additional structural data given in the ESI[†]).

All nitroxide biradicals **1c**, **2c**, **1d**, **3d**, **4d**, and **5d** under study possess a planar backbone – the necessary prerequisite for the propagation of weak intramolecular magnetic interactions. Importantly, in such biradical models the torsion angles θ (see Table 1) play a central role in the modulation of magnetic exchange interactions.

Not surprisingly, similar torsion angles θ of about $\sim 24^{\circ}$ result in a nearly identical degree of conjugation.^{11,15} Consequently, a comparable spin polarization and close values of the exchange integrals were expected for most of the obtained biradical models (see for comparison Table 1). In contrast to the described situation, the radical units in nitronyl nitroxide **2c** were far more twisted ($>50^{\circ}$). From this crystal structure analysis it was assumed that nitronyl biradical **2c** would exhibit a unique behavior among the compounds investigated here.

Biradical **1c** adopts a triclinic space group with an inversion centre residing in the middle of the acetylene bridge (Fig. 2). Remarkably, in the asymmetric unit there are two crystallographically independent molecules with a nearly equal geometry. The dihedral angles of the mean plane of the imidazolidine ring and the two coplanar pyridine rings were found to be $\approx 25^{\circ}$ for O1–N2–C7 (O2N3–C7) towards C5 and 22° for O3N5–C20 (O4–N6–C20) towards C18 (see Table 1). Here, the N(2)–O(1) 1.280(1), N(3)–O(2) 1.278(2), N(5)–O(3) 1.279(1), and N(6)–O(4) 1.272(2) Å bond lengths occur in the typical range for the nitroxides.^{11,14,15} The N(2)–C(7) 1.355(2), N(2)–C(11) 1.503(1), N(3)–C(7) 1.351(1), N(3)–C(8) 1.503(2), N(5)–C(20) 1.358(2), N(5)–C(24) 1.502(1), N(6)–C(20) 1.354(2), and N(6)–C(21) 1.497(1) Å bond distances are elongated due to the short intermolecular contacts that stabilize the crystal packing (for instance, the ones formed by N(6)O(4)).

Scheme 3 Synthesis of nitroxide biradicals **1c** and **1d**. Reagents and conditions: (i) BSA, toluene, reflux under Ar, 4–6 h; (ii) NaIO_4 , $\text{CH}_2\text{Cl}_2\text{-H}_2\text{O}$, $0\text{--}5\text{ }^{\circ}\text{C}$, 30–40 min; (iii) MnO_2 , CH_3NO_2 , 35 min.

Table 1 Selected bond lengths and dihedral angles for the synthesized biradicals

| Biradical | d , Å | θ , deg |
|-----------|-------------------|-----------------|
| 1c | 1.4513(15) on C18 | 21.62(9) |
| | 1.4564(15) on C5 | 24.84(10) |
| 2c | 1.472(18) | 53.72(11) |
| 1d | 1.4743(12) on C25 | 23.16(12) |
| | 1.4717(12) on C5 | 24.85(9) |
| 3d | 1.471(2) | 20.2(2) O1 |
| 4d | | 15.35(18) at O2 |
| | 1.473(2) | 13.57(19) |
| 5d | 1.4754(17) | 5.97(12) |

Fig. 2 Molecular structure (top) of biradical **1c** with ORTEP drawn at the 50% probability level and crystal packing (bottom) with emphasized short contacts.

The intermolecular contacts between NO groups of the first molecule with the pyridine rings ($O4 \cdots C1'$ 3.036, $O4 \cdots C2'$ 3.135 Å) of the neighboring biradical lead to V-shaped alignment of dimers (Fig. 2 and Fig. S1, ESI[†]).

Biradical **2c** crystallizes in the $P2_1/c$ space group and its molecular structure is shown in Fig. 3. Compound **2c** features a transoid arrangement with an inversion center of symmetry located in the C1–C1' bond, which is typical for the derivatives containing acetylene bridges (Fig. 3). In general, the structural data of **2c** are rather similar to those described for the other nitronyl nitroxide biradicals in the literature (Table 1 and Table S1, ESI[†]).^{11,14} A remarkable difference is found in the largely increased torsion between the pyridyl ring and the imidazolidine fragment O1–N2–C7 (O2–N3–C7) with a dihedral angle of 53.72(11) (Fig. 3).

The crystal packing of **2c** presents a beautiful example where the bidentate character of the nitronyl nitroxide fragment plays a major role in the spatial arrangement of the biradical chains. Here, the molecules of **2c** form infinite zig-zag ribbons along the *b* axes (Fig. 3 and Fig. S3, ESI[†]). Notably, the neighboring molecules are organized in an alternate fashion, placing NN groups next to the pyridine plane and, thereby, stabilizing the crystal packing (Fig. S3, ESI[†]).

Imino biradical **1d** crystallizes in the triclinic space group $P\bar{1}$. There are two independent centrosymmetric half molecules in the asymmetric unit cell. (Fig. 4). The main structural characteristics are similar to those described for the corresponding nitronyl nitroxide derivative **1c**. Thus, the pyridine rings form angles of $\approx 23^\circ$ and $\approx 25^\circ$ with the imidazolidine plane (Table 1). The N(2)–O(1) 1.269(1), N(221)–O(211) 1.277(2),

Fig. 3 Molecular structure (top) and crystal packing (bottom) of biradical **2c** (view along the *a* axes).

and N(222)–O(212) 1.257(5) Å bond distances featured minor differences.

The packing arrangement of radical dimers **1d** is shown in Fig. 4, and can be described as a ladder-like structure with biradicals of the first kind forming a stair, and nitroxides of the second type extending from both sides of each step (Fig. S4, ESI[†]). The structure is supported by numerous hydrogen bonds

Fig. 4 Molecular structure (top) with two biradical molecules per asymmetric unit of biradical **1d** and short contacts and π -stacking specified in fragments of molecules from crystal packing.

arising from the pyridine π -bridges and the imino nitroxide chelating units. The short contacts of the NO groups and the hydrogen atoms of the pyridine core $O211 \cdots H261' = 2.456$, $O212 \cdots H261' = 2.538$ Å (Fig. 4) seems to be the most important. The shortest interchain distances of 3.352 Å ($C6 \cdots C25'$) are found between the two neighboring diazotolane bridges (Fig. 4). The closest intermolecular contacts between NO groups and a pyridine ring are slightly larger, and are within the range of ~ 2.4 – 2.7 ($O1 \cdots H41'$, $O1 \cdots H31'$, respectively) and ~ 3.1 Å ($O1 \cdots C4'$).

Imino biradicals **3d** and **4d** feature isomorphic crystal structures. Thus, they possess the $P2_1/n$ space group with a center of symmetry located in the middle of the aromatic C–C' bond (Fig. 5 and Fig. S4, ESI†). The biphenyl bridge in **3d** is surprisingly planar, and the dihedral angle between the mean plane of the benzene ring and the imidazolidine moiety is only 20.2° . **3d** is slightly disordered, since the five membered ring can flip around 180° such that the two NO groups could be oriented 'E' or 'Z' with 50% probability. The N(1)–O(1) 1.226(3) and N(2)–O(2) 1.213(3) Å bond lengths are in the standard range.¹⁵

Naturally, for the isomorphic imino nitroxide derivatives **3d** and **4d** the main structural characteristics are very similar.^{14,27} Thus, in **4d** the O–N–C–N–O moiety is planar, with the N(3)–O(2) bond being slightly shorter than N(2)–O(1) 1.167(4) and 1.215(3) Å, respectively (Fig. S4, ESI†). Furthermore, in the asymmetric unit of **4d** there are two crystallographically independent forms with the ratio of $\sim 2:3$ belonging to different biradical chains (Fig. S4, ESI†).

An important feature already mentioned for the other biradicals of the current series is the abundance of close intermolecular contacts between the N–O entities and the aromatic moieties in the asymmetric unit. In particular, the hydrogen bonding $O1 \cdots H31' = 2.580$, $O1 \cdots H123' = 2.696$, and $O1 \cdots C3' = 3.177$ Å between the neighboring oxygen atoms and phenyl rings in **3d** defines the formation of ribbon-like structures which are

Fig. 5 Molecular structure (top) and crystal packing (bottom) of biradical **3d**.

Fig. 6 Molecular structure (top) and crystal packing (bottom) of biradical **5d**.

further organized in a zig-zag pattern. Likewise, multiple oxygen contacts (*i.e.* $O1 \cdots H91' = 2.302$, $O2 \cdots H51' = 2.473$, $O2 \cdots H93' = 2.600$, $O1 \cdots C9' = 3.199$ and $O2 \cdots C5' = 3.085$ Å) accompany the molecular ordering in the case of imino derivative **4d** (Fig. S4, ESI†). Notably, the neighboring chains in **4d** are connected with close $O2 \cdots O2' = 2.801$ Å contacts.

Imino nitroxide biradical **5d** crystallizes in a monoclinic space group with $P2_1/n$ symmetry. The structure of compound **5d** is shown in Fig. 6. In contrast to the previously described biradicals compound **5d** has surprisingly small torsion angles between the radical unit and the adjacent phenyl ring of only about 6° .³⁰ The overall tolane backbone is fairly planar. The N(2)–O(1) 1.271(1) Å bond distances are similar for this type of compound.

The oxo atoms in **5d** act as bridging ligands ($O1 \cdots H141' = 2.622$, $O1 \cdots H131' = 2.654$ Å) connecting the neighboring biradical molecules into 1D zig-zag shaped chain structures in the crystal cell. These radical ribbons are then piled up along the *b* crystallographic axis (Fig. S5, ESI†), using $C7 \cdots C10' = 3.381$ Å close contacts to stabilize the packing (Fig. 6 and Fig. S7, ESI†).

Magnetic characterization

To gain a more complete picture of the influence of a given π -spacer on the electronic properties, and especially on the intra- and inter-dimer exchange couplings, DFT calculations were performed. To get a first idea on the sizeable changes of the exchange interaction in the studied biradical models, geometry optimization with the B3LYP hybrid function and the 6-31G* basis set was carried out.³¹ Then the broken symmetry approach (BS) for the singlet and triplet states with the BLYP functional (to avoid Hartree–Fock contamination) and the same basis set were applied.¹² Therefore, the direct exchange interaction for a weakly coupled spin dimer can be described as $J/k_B = E(\text{BS}) - E(T)$, since the spin expectation

Table 2 Calculated $J_{\text{intra}}^{\text{calc}}$ and experimentally obtained $J_{\text{intra}}^{\text{exp}}$ intra-dimer exchange coupling constants. $zJ_{\text{inter}}^{\text{calc}}$ describes the inter-dimer coupling, where z is the number of the nearest neighbors. T_{max} corresponds to the maximum in the $\chi_{\text{mol}}(T)$ plot

| Biradical | T_{max} [K] | $J_{\text{intra}}^{\text{calc}}$ ^a [K] | $J_{\text{intra}}^{\text{calc}}$ ^b [K] | $J_{\text{intra}}^{\text{exp}}$ [K] | $zJ_{\text{inter}}^{\text{exp}}$ [K] |
|-----------|----------------------|---------------------------------------------------|---------------------------------------------------|-------------------------------------|--------------------------------------|
| 1c | 6.8 | -19.6 | -9.8 | -5.4 ± 0.2 | -1.4 ± 0.4 |
| 2c | 53 | -2.4 | -3.1 | -12.0 ± 3.0^c | -42.4 ± 1.7^c |
| 1d | — | -2.4 | -1.1 | < -1.5 | — |
| 3d | 4.2 | -4.7 | -5.0 | -3.3 ± 0.1 | -2.0 ± 0.5 |
| 4d | 3.2 | -3.2 | -3.6 | -2.5 ± 0.1 | -5.8 ± 1.4 |
| 5d | 2.8 | -2.6 | -1.6 | -2.2 ± 0.1 | -0.5 ± 0.1 |

^a Optimized geometries were obtained from DFT calculations (B3LYP, 6-31G*), then single point calculations for the energy of the broken symmetry and the triplet state were applied (UBLYP, 6-31G* for the evaluation of J).³¹ ^b The exchange interactions were evaluated for X-ray crystal structures applying the broken symmetry approach with the BLYP functional and the 6-31G* basis set. ^c Note that dominant magnetic exchange in **2c** is between two adjacent NN units belonging to different biradicals (for details see the text and Fig. 3).

values $\langle S^2(\text{BS}) \rangle$ and $\langle S^2(T) \rangle$ for the broken symmetry configuration are close to 1 and for the triplet configuration they are close to 2 such that their difference is close to unity.³² Notably, in the case of antiferromagnetic interactions J takes negative values. The calculations were then redone in accordance with the X-ray geometries, as listed in Table 2.

Applying a Quantum Design SQUID magnetometer the temperature dependence of the molar magnetic susceptibilities $\chi_{\text{mol}}(T)$ of microcrystalline samples **1c**, **2c**, **1d**, **3d**, **4d**, and **5d** was determined in the range of $2 \text{ K} \leq T \leq 270 \text{ K}$ in a magnetic field $B = 1 \text{ T}$. The obtained data were corrected for the temperature-independent diamagnetic core contribution of the constituents.³³ The magnetic contribution of the sample holder was determined in an independent experiment without a sample. The results are graphically displayed in the form of $\chi_{\text{mol}}T$ vs. T in the main panel, and χ_{mol} vs. T in the insets of Fig. 7 and 8 and in the ESI† (Fig. S8). AC-susceptibility measurements (χ_{ac}) were performed only on **5d** as a function of the magnetic field at $T = 0.028 \text{ K}$ using an ultra-high resolution AC-susceptometer adapted to a ³He-⁴He top-loading dilution refrigerator. The compensated-coil susceptometer was optimized for measuring small single crystals in the mg range.

Generally, all the biradicals under investigation (**1c**, **2c**, **1d**, **3d**, **4d**, **5d**) featured a similar magnetic behavior in the studied temperature range. The observed $\chi_{\text{mol}}T$ values at 300 K of the nitroxides are around $0.7 \text{ cm}^3 \text{ K mol}^{-1}$. Importantly, experimental data are rather close to the theoretical value of $0.75 \text{ cm}^3 \text{ K mol}^{-1}$, which is expected for the two uncoupled spin $S = 1/2$ units (indicated by the broken line in Fig. 7). This indicates the high quality of the studied single crystals.

As a typical example, $\chi_{\text{mol}}T(T)$ of NN-biradical **1c** is shown in Fig. 7. Upon decreasing the temperature $\chi_{\text{mol}}T$ features an approximately linear moderate decrease down to $\sim 120 \text{ K}$ followed by a more pronounced drop below $\sim 50 \text{ K}$. This overall behavior reflects the dominant antiferromagnetic intra-dimer coupling J_{intra} . The inset of Fig. 7 shows the molar magnetic susceptibility as a function of temperature. The Bleany–Bowers equation³⁴ for a model of an isolated dimer χ_{iso} with a mean-field correction was

Fig. 7 $\chi_{\text{mol}}T$ as a function of temperature (solid orange circles) of **1c**. The black broken line indicates the theoretical value of $0.75 \text{ cm}^3 \text{ K mol}^{-1}$, expected for the two uncoupled spin $S = 1/2$ entities. Inset: Molar susceptibility χ_{mol} as a function of temperature (solid green circles) in a semilog representation, and a theoretical fit with a mean-field correction (red solid line).³³

Fig. 8 $\chi_{\text{mol}}T$ as a function of temperature (solid orange circles) of **2c**. The black broken line indicates the theoretical value of $0.75 \text{ cm}^3 \text{ K mol}^{-1}$, expected for the two uncoupled spin $S = 1/2$ entities. Inset: Molar susceptibility χ_{mol} as a function of temperature (solid green circles), and a theoretical fit with a mean-field correction (red solid line),³³ including a Curie term corresponding to $S = 1/2$ entities.

applied to fit the experimental data (solid line in the inset of Fig. 7). Using this fitting the sizes of the intra-dimer J_{intra} and inter-dimer zJ_{inter}' (where z is the number of the nearest neighbors) coupling constants were extracted:

$$\chi_{\text{mol}} = \chi_{\text{iso}} / [1 - (zJ' \cdot \chi_{\text{iso}} / Ng^2 \mu_B^2)] \quad (1)$$

Thus, for **1c** an experimental intra-dimer coupling constant $J_{\text{intra}}/k_B = -5.4 \pm 0.2 \text{ K}$ was obtained. This value is in tangible agreement with the coupling constant acquired from the broken-symmetry approach (Table 2). It should be mentioned that the experimental and theoretical J_{intra} values of **1c** are very similar to the ones reported for tolane NN ($J_{\text{intra}}/k_B = -4.8 \text{ K}$).¹¹

In light of this it is reasonable to assume that a mere substitution of N for C in position X (as indicated in Fig. 1), if it does not severely affect the geometry of a given crystal structure, has no practical influence on the magnetic interactions.

An unexpected result was acquired for NN derivative **2c** where N was substituted with C in the Y position (Fig. 1). For this system the DFT calculations predict J_{intra} values of a few Kelvin, *i.e.* similar to those found for the other materials under investigation. The magnetic properties of **2c** determined experimentally are shown in Fig. 8. The $\chi_{\text{mol}}T$ data decreased gradually and leveled off around 20 K at a small value of approximately $0.02 \text{ cm}^3 \text{ K mol}^{-1}$. In the inset of Fig. 8 a broad maximum in χ_{mol} at 53 K is clearly visible. From a theoretical fit³³ corrected with a Curie term for uncoupled $S = 1/2$ entities (solid red line in the inset of Fig. 8), an inter-dimer coupling constant of $J_{\text{inter}}/k_{\text{B}} = -42.4 \text{ K}$ was obtained. This is significantly larger than J_{intra} of **1c** and tolane NN in ref. 11.

This observation is conceivable in terms of the crystal structure peculiarities. As described above, the radical units in nitronyl nitroxide **2c** are far more twisted ($\sim 53^\circ$) in comparison to other biradical models described here. The further analysis of the X-ray data revealed exceptionally short contacts of $\sim 3.51 \text{ \AA}$ between two neighboring NO fragments in 3,3'-diazatolane nitronyl nitroxide **2c** (Fig. S7, ESI[†]). Apparently, these short contacts are responsible for the unpredicted strong antiferromagnetic exchange interactions found in the solid. Taking only these intermolecular interactions into account and replacing the second radical unit by hydrogen, the value $J_{\text{inter}}/k_{\text{B}} = -45.6 \text{ K}$ was calculated, which was very close to the experimentally obtained value of $-42.4 \pm 1.7 \text{ K}$ (Table 2). Such short inter-dimer distances between spin centers could not be found in the other biradicals.

In accordance with the theoretical predictions and crystal structure analysis IN biradicals **1d**, **3d**, **4d** and **5d** featured weak antiferromagnetic intramolecular coupling. Their intra-dimer exchange constants are listed in Table 2 (see also Fig. S8, ESI[†]). Interestingly, in the case of IN-biradicals **3d** and **4d** the N-heteroatomic substitution has barely affected their magnetic properties in accordance to the previous statement. From the experimental data recorded for imino biradical **1d** no clear maximum could be resolved, indicating an extremely weak intra-dimer coupling constant $< -1.5 \text{ K}$.

Remarkably, a closer examination of the low-temperature ($T < J_{\text{intra}}/k_{\text{B}}$) susceptibility data for IN-biradical **5d** revealed a significant deviation from the isolated-dimer model. Typically, magnetization of the isolated-dimer systems changes in a step-wise manner at the saturation field B_{s} and temperatures $T < J_{\text{intra}}/k_{\text{B}}$. Such field-temperature induced transitions correspond to the alteration in the spin-state population of the dimers, namely, the occupation of the low-lying triplet state. This phenomenon is reflected in the form of a single peak in susceptibility χ , the field derivative of magnetization. Fig. 9 shows the AC-susceptibility of IN biradical **5d** as a function of the magnetic field at 0.028 K (right scale) together with the magnetization of the material at the same temperature (left scale).

Fig. 9 Magnetization $M(B)$ of **5d** (solid red line, left scale) at 28 mK normalized to the saturation magnetization together with the magnetic AC-susceptibility $\chi_{\text{ac}}(B)$ (orange full circles, right scale).

The AC susceptibility was measured only for IN biradical **5d** since only for this sample a large single crystal was available. Polycrystalline samples have been shown to be critical for their intercrystalline contacts and depend on their powder to crystallinity content and several mg are still needed. The data highlight a well-pronounced double-peak feature in χ_{ac} , an evidence of a field-induced ordered state between $B_{\text{c1}} = 1.8 \text{ T}$ and $B_{\text{c2}} = 4.3 \text{ T}$ at 0.028 K. Such field-induced phases are expected for a coupled-dimer system where the lower edge of a band of magnetic excitations crosses the ground state at B_{c1} . Here, B_{c2} corresponds to the saturation field B_{s} where the full magnetization of the system is obtained. The magnetization exhibits no hysteretic behavior. This feature is attributed to small magnetic intermolecular interactions between the neighboring biradical molecules mediated *via* hydrogen bonds. The strength of these interactions depends on the distance and the relative orientation of the radicals.^{35,36} The anomalies at the critical fields B_{c1} and B_{c2} are much sharper than the one found in a quasi-2D system.¹¹ More likely, the inter-dimer coupling in **5d** has a 3D character, and therefore, this field-induced ordered phase can be described in terms of a BEC of triplons.

Experimental section

Materials and methods

All chemicals and reagents were used as received from commercial sources (Acros Organics, Aldrich, Fluka, Lancaster, Merck and Strem) without additional purification. Solvents for synthesis were used as received, unless otherwise mentioned. ESR spectra were recorded in dilute, oxygen-free solutions in toluene, concentrations $\sim 10^{-4} \text{ mol L}^{-1}$, using a Bruker ESP300 E X-band spectrometer equipped with an NMR gaussmeter (Bruker ER035), a frequency counter (Bruker ER041XX) and a variable temperature control continuous flow N_2 cryostat (Bruker B-VT 2000). The g -factor corrections were obtained using DPPH ($g = 2.0037$) as the standard. UV-Vis spectra were recorded in toluene solutions with a PerkinElmer spectrometer (UV/Vis/NIR Lambda 900) using a 1 cm optical path quartz cell at room temperature,

unless otherwise specified. ^1H and ^{13}C NMR spectra were recorded on a Bruker DPX 250, Bruker DMX 300 spectrometer. Solid powders were pressed and IR spectra of the samples were recorded as they were (Nicolet 730 FT-IR spectrometer). Mass spectra (FDMS) were obtained on a VG Instruments ZAB-2 mass spectrometer. Elemental analyses were performed at the University of Mainz, Faculty of Chemistry and Pharmacy on a Foss Heraeus Varieo EL. The melting points were measured on a Büchi B-545 apparatus (uncorrected) by using open-ended capillaries. Crystallographic data for the reported structures of the biradicals have been deposited at the Cambridge Crystallographic Data Centre. ‡ 2,3-Bis(hydroxyamino)-2,3-dimethylbutane (BHA) synthesis was described elsewhere.^{11,15}

A1. General procedure for Sonogashira–Hagihara coupling reaction. An aryl bromide (21.7 mmol, 1 eq.) was transferred into a flame-dried flask in an argon stream. A mixture of dry DMF/ NEt_3 (50 mL, 1 : 1) solvents was added through the rubber septum. The solution was carefully deaerated by purging with argon for 20–25 min, and a catalytic mixture of $\text{Pd}(\text{PPh}_3)_2\text{Cl}_2$ (1.1 mmol, 0.05 eq.), PPh_3 (2.2 mmol, 0.1 eq.), and CuI (1.1 mmol, 0.05 eq.) was added at once. The resulting mixture was slightly heated (to 45 °C) and ethynyltrimethylsilane (32.6 mmol, 1.5 eq.) was added through the septum. After that the heating was increased to 80 °C. A white precipitate began to form after ~15 min of heating. After the reported time (4 to 16 h), the mixture was cooled to ambient temperature, and the crystalline white solid of triethylamine hydrobromide was isolated by filtration. The orange-brown filtrate was concentrated, mixed with NH_4Cl saturated aqueous solution (50 mL), and extracted with dichloromethane or diethyl ether (3 × 40 mL). The organic fractions were combined, dried over magnesium sulfate, and concentrated with silica gel *in vacuo*. The residue was purified using column chromatography.

A2. Using the same set-up and the catalyst/reagent ratio a mixture of dry $\text{NEt}_3/\text{CH}_3\text{CN}$ (1 : 1) as the solvent media was preferred. Here, after 5 minutes of stirring at room temperature formation of triethylamine hydrobromide salt was observed. The light yellow reaction mixture was stirred at room temperature for 17–19 h. The work-up was done in accordance with protocol A1.

2-Bromo-5-pyridinecarbaldehyde (7). 2,5-Dibromopyridine **6** (10 g, 42.2 mmol) was charged into a flame-dried flask, evacuated and kept under argon. Dry diethylether (250 mL) was added, and the resulting solution was cooled to –78 °C in a dry ice/acetone bath. Then *n*-BuLi (34 mL, 1.6 M in hexane, 53.8 mmol) was added dropwise within 20–25 min. Upon addition of *n*-BuLi the resulting solution turned red. The temperature (–78 °C) was kept constant for further 45 min, and then dry dimethylformamide (4.7 mL, $d = 0.94 \text{ g mL}^{-1}$, 60.3 mmol) was added dropwise within 15 min. The mixture turned deep red. The temperature (–78 °C) was maintained for further 90 min, and then slowly increased. After that 3% HCl (100 mL) was added. The resulting mixture was

stirred for 20 min. Diethylether was concentrated *in vacuo*. To the oily residue 60 mL of dichloromethane was added, and the mixture was neutralized with solid NaHCO_3 . The organic phase was separated and the water layer was extracted with dichloromethane (3 × 60 mL). Combined organic extracts were dried over MgSO_4 , and the solvent was evaporated. Crystals were filtered and washed carefully with hexane (3 × 20 mL). The filtrate was reduced to a small volume (*ca.* 2 mL), and purified on a flash column (SiO_2 , dichloromethane). Aldehyde **7** was obtained in 72% total yield. $^1\text{H-NMR}$ (CDCl_3 , 250 MHz, 298 K, 16 scan), δ ppm: 7.66 (d, 1H, $^3J = 8 \text{ Hz}$, H-3), 8.01 (dd, 1H, $^3J = 8 \text{ Hz}$, H-4), 8.82 (s, 1H, H-6), 10.08 (s, 1H, –CHO). $^{13}\text{C-NMR}$ (CDCl_3 , 63 MHz, 298 K, 256 scan) δ ppm: 129.4 (C-3), 131 (C-5), 137.9 (C-4), 148.7 (C-2), 152.9 (C-6), 189.9 (–CHO). MS-FD (70 eV, CH_2Cl_2) m/z : 187.3 (M^+), MW calculated $\text{C}_6\text{H}_4\text{BrNO}$ (MW^+) 186.01.

2-Bromo-5-[1,3]-dioxolan-2-yl-pyridine (8). Starting compound **7** (5 g, 26.85 mmol) was charged into a flask together with benzene (100 mL), ethyleneglycol (2.7 mL, 48.5 mmol) and a catalytic amount of *para*-toluene-sulfonic acid (0.4 g, 2.1 mmol). The solution was heated to reflux with Deane-Stark for 20 h. Then the reaction mixture was cooled down to rt, and neutralized with NaHCO_3 aqueous solution, and the phases were separated. The aqueous layer was extracted with small portions of benzene (3 × 15 mL). Benzene extracts were collected, dried over MgSO_4 and filtered. The solvent was evaporated under reduced pressure. Compound **8** was obtained as a yellowish oil in 85% yield (5.4 g), and was used further without additional purification. $^1\text{H-NMR}$ (CDCl_3 , 250 MHz, 298 K, 16 scan), δ ppm: 3.92 (m, 4H, – CH_2), 5.71 (s, 1H, H-7), 7.34 (d, 1H, $^3J = 8 \text{ Hz}$, H-3), 7.62 (dd, 1H, $^3J = 8 \text{ Hz}$, H-4), 8.47 (s, 1H, H-6). $^{13}\text{C-NMR}$ (CDCl_3 , 63 MHz, 298 K, 256 scan), δ ppm: 64.4 (– CH_2), 100.2 (C-7), 126.9 (C-3), 132.4 (C-5), 135.9 (C-4), 142 (C-2), 147.9 (C-6). MS-FD (70 eV, CH_2Cl_2) m/z : 231.2 (M^+), MW calculated $\text{C}_8\text{H}_8\text{BrNO}_2$ (MW^+) 230.06.

2-Ethynyl-trimethyl-silyl-5-[1,3]-dioxolan-2-yl-pyridine (9). Derivative **9** was synthesized according to the synthetic procedure A1. Purification on a silica gel column with dichloromethane/hexane as the eluent (3 : 2) afforded precursor **9** in 89% yield. $^1\text{H-NMR}$ (CDCl_3 , 250 MHz, 298 K, 16 scan), δ ppm: 0.28 (s, 9H, – CH_3), 4.09 (m, 4H, – CH_2), 5.85 (s, 1H, H-7), 7.47 (d, 1H, $^3J = 8 \text{ Hz}$, H-3), 7.74 (dd, 1H, $^3J = 8 \text{ Hz}$, H-4), 8.65 (s, 1H, H-6). $^{13}\text{C-NMR}$ (CDCl_3 , 63 MHz, 298 K, 256 scan), δ ppm: 0 (– CH_3), 67.1 (– CH_2), 94.8 (C-9), 102.2 (C-7), 104.1 (C-8), 126.7 (C-3), 132.6 (C-5), 134.9 (C-4), 143.4 (C-2), 148.6 (C-6). MS-FD (70 eV, CH_2Cl_2) m/z : 247.1 (M^+), MW calculated $\text{C}_{13}\text{H}_{17}\text{NO}_2\text{Si}$ (MW^+) 247.37.

2-Ethynyl-5-[1,3]-dioxolan-2-yl-pyridine (10). A solution of 2-ethynyl-trimethyl-silyl-5-[1,3]-dioxolan-2-yl-pyridine **10** (0.33 g, 1.3 mmol) in THF (25 mL) was treated with 1 N NaOH (50 mL) under argon at 5 °C (ice/water bath). After 35 min the reaction was complete (according to the TLC analysis of the reaction mixture aliquots). The solvent was evaporated under reduced pressure, and brine (50 mL) was added to the residue. The aqueous layer was extracted with dichloromethane (3 × 60 mL). The combined organic fractions were dried over MgSO_4 and concentrated *in vacuo*. The so-obtained compound **10** (89% yield)

‡ Crystallographic data for the reported structures of biradicals **1c**, **2c**, **1d**, **3d**, **4d** and **5d** have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC 823716, 816632, 816630, 823717, 858078, 810139, respectively.

was used for the next step without additional purification. $^1\text{H-NMR}$ (CDCl_3 , 250 MHz, 298 K, 16 scan), δ ppm: 3.2 (s, 1H, H-9), 4.11 (m, 4H, $-\text{CH}_2$), 5.88 (s, 1H, H-7), 7.51 (d, 1H, $^3J = 8$ Hz, H-3), 7.78 (dd, 1H, $^3J = 8$ Hz, H-4), 8.69 (s, 1H, H-6). $^{13}\text{C-NMR}$ (CDCl_3 , 63 MHz, 298 K, 256 scan), δ ppm: 65.4 ($-\text{CH}_2$), 72.8 (C-9), 81.4 (C-8), 101.8 (C-7), 127.4 (C-3), 134.2 (C-5), 134.7 (C-4), 142.5 (C-2), 149.4 (C-6). MS-FD (70 eV, CH_2Cl_2) m/z : 175.3 (M^+), MW calculated $\text{C}_{10}\text{H}_9\text{NO}_2$ (MW^+) 175.18.

2,2'-Ethynyl-1,2-diylbis(pyridine-5-carbaldehyde) (1a). Sonogashira cross-coupling between precursors **8** and **10** was realized following methodology A2. As the major product 1,2-bis(5-(1,3-dioxolan-2-yl)pyridine-2-yl)ethyne was isolated in 72% yield using flash chromatography (SiO_2 , dichloromethane). $^1\text{H-NMR}$ (CDCl_3 , 250 MHz, 298 K, 16 scan), δ ppm: 4.01 (m, 8H, $-\text{CH}_2$), 5.8 (s, 2H, H-7), 7.56 (d, 2H, $^3J = 8$ Hz, H-3), 7.72 (dd, 2H, $^3J = 8$ Hz, H-4), 8.65 (s, 2H, H-6). $^{13}\text{C-NMR}$ (CDCl_3 , 63 MHz, 298 K, 256 scan), δ ppm: 65.8 ($-\text{CH}_2$), 88.5 (C-8), 101.9 (C-7), 127.8 (C-3), 133.9 (C-5), 134.9 (C-4), 143.5 (C-2), 149.1 (C-6). MS-FD (70 eV, CH_2Cl_2) m/z : 324.5 (M^+), MW calculated $\text{C}_{18}\text{H}_{16}\text{N}_2\text{O}_4$ (MW^+) 324.33.

Next, to the solution of the corresponding dioxolane precursor (0.38 g, 1.35 mmol) in an acetone–water mixture (7 : 1, 40 mL) *para*-toluene-sulfonic acid (52 mg, 0.027 mmol, 2 mol%) was added. The progress of the reaction was monitored by TLC (SiO_2 , hexane/ethyl acetate, 3 : 1). After 84 h of stirring at room temperature the reaction was complete. Acetone was evaporated, and the residue was diluted with dichloromethane (30 mL). The organic layer was separated, and the water phase was extracted with dichloromethane (3 \times 30 mL). The combined organic extracts were dried over MgSO_4 . The solvent was removed *in vacuo* giving 0.26 g (81%) of dialdehyde **1a** as a yellow solid. $^1\text{H-NMR}$ ($(\text{CD}_3)_2\text{SO}$, 250 MHz, 298 K, 16 scan), δ ppm: 8.01 (d, 2H, $^3J = 8$ Hz, H-2), 8.37 (dd, 2H, $^3J = 8$ Hz, H-3), 9.19 (s, 2H, H-6), 10.20 (s, 2H, $-\text{CHO}$). $^{13}\text{C-NMR}$ ($(\text{CD}_3)_2\text{SO}$, 63 MHz, 298 K, 256 scan), δ ppm: 90.1 (C-8), 128.8 (C-3), 131.1 (C-5), 137.3 (C-4), 145.7 (C-2), 152.2 (C-6), 192.2 ($-\text{CHO}$). MS-FD (70 eV, CH_2Cl_2) m/z : 236.3 (M^+), MW calculated $\text{C}_{14}\text{H}_8\text{N}_2\text{O}_2$ (MW^+) 236.23.

5-Bromo-2-pyridinecarbaldehyde (11). *n*-BuLi (48 mL, 1.6 M solution in hexane, 76.8 mmol) and 50 mL of dry toluene were transferred to a flame-dried flask filled with argon through the rubber septum. The solution was cooled to -78 °C in a dry ice/acetone bath, and a solution of 2,5-dibromopyridine **6** (15 g, 63 mmol) in dry toluene (300 mL) was added dropwise within 1.5 h. Upon addition of the starting compound **6** to the mixture the color changed from colorless to yellow. The mixture was stirred at -78 °C for 30 min, and the temperature was allowed slowly to increase until -65 °C. Then the solution was cooled again to -78 °C, and dry dimethylformamide (5.89 mL, $d = 0.94$ g mL^{-1} , 75.8 mmol) was added slowly dropwise within 20 min. The mixture was allowed to stir overnight, and then decomposed with 3% HCl (100 mL). The organic layer was separated, and the water was extracted with dichloromethane (4 \times 50 mL). The combined organic extracts were washed with NaHCO_3 , dried over MgSO_4 and the solvents were evaporated *in vacuo*. The oily residue was purified through a flash column (SiO_2 , petroleum ether/ethyl acetate, 100 : 3). 5-Bromo-2-pyridinecarbaldehyde **11** was synthesized in 49% yield. $^1\text{H-NMR}$ (CDCl_3 ,

250 MHz, 298 K, 16 scan), δ (ppm): 7.8 (d, 1H, H-6), 7.9 (dd, 1H, $^3J = 8$ Hz, H-4), 8.78 (d, 1H, H-3), 9.97 (s, 1H, $-\text{C}=\text{O}$). $^{13}\text{C-NMR}$ (CDCl_3 , 63 MHz, 298 K, 256 scan), δ ppm: 122.7 (C-5), 126.2 (C-3), 139.9 (C-4), 151.1 (C-2), 151.5 (C-6), 192.3 ($-\text{CHO}$). MS-FD (70 eV, CH_2Cl_2) m/z : 187.3 (M^+), MW calculated $\text{C}_6\text{H}_4\text{BrNO}$ (MW^+) 186.01.

5-Ethynyl-trimethyl-silyl-2-formylpyridine (12). Trimethylsilyl derivative **12** was obtained in 87% yield (2.37 g) following general procedure A1 after the purification on a silica gel chromatographic column (ethyl acetate/hexane, 3 : 100). $^1\text{H-NMR}$ (CDCl_3 , 250 MHz, 298 K, 16 scan), δ ppm: 0.26 (s, 9H, $-\text{CH}_3$), 7.86 (d, 2H, $^3J = 2$ Hz, H-3, H-4), 8.77 (s, 1H, H-4), 8.65 (s, 1H, H-6), 10.02 (s, 1H, $-\text{C}=\text{O}$). $^{13}\text{C-NMR}$ (CDCl_3 , 63 MHz, 298 K, 256 scan), δ ppm: 0 ($-\text{CH}_3$), 98.8 (C-8), 101.9 (C-7), 121.1 (C-3), 122.4 (C-5), 140.4 (C-4), 150.8 (C-2), 151.7 (C-6), 192.7 ($-\text{C}=\text{O}$). MS-FD (70 eV, CH_2Cl_2) m/z : 202.7 (M^+), MW calculated $\text{C}_{11}\text{H}_{13}\text{NOSi}$ (MW^+) 203.31.

5-Ethynyl-2-formylpyridine (13). A solution of **12** (1.43 g, 7 mmol) and K_2CO_3 (0.46 g, 3.33 mmol) in a deaerated THF/water mixture (80 mL, 1 : 1 v/v) was stirred at rt for 1.5 h. Brine was added to the mixture, the organic layer was separated, and the water phase was extracted with Et_2O (4 \times 30 mL). Combined organic extracts were dried over Na_2SO_4 , and the solvents were evaporated under reduced pressure. The light-brown solid was washed with a hot hexane/acetone mixture ($\sim 20 : 1$) to give a pale yellow precipitate in 51% yield (0.47 g). $^1\text{H-NMR}$ (CDCl_3 , 250 MHz, 298 K, 16 scan), δ ppm: 3.36 (s, 1H, H-8), 4.78 (d, 2H, $^3J = 8$ Hz, H-3, H-4), 8.79 (t, 1H, $^3J = 8$ Hz, H-6), 10.0 (s, 1H, $-\text{C}=\text{O}$). $^{13}\text{C-NMR}$ (CDCl_3 , 63 MHz, 298 K, 256 scan), δ ppm: 78.7 (C-7), 83.6 (C-8), 119.9 (C-3), 122.7 (C-5), 139.2 (C-4), 150.4 (C-2), 152.0 (C-6), 191.4 ($-\text{CHO}$). MS-FD (70 eV, CH_2Cl_2) m/z : 130.3 (M^+), MW calculated $\text{C}_8\text{H}_5\text{NO}$ (MW^+) 131.13.

5,5'-Ethynyl-1,2-diylbis(pyridine-2-carbaldehyde) (2a). Compound **2a** was synthesized applying Sonogashira–Hagihara coupling methodology A1 towards precursors **11** and **13**. After evaporation of the solvent, the residue was diluted with chloroform (40 mL), and washed with NH_4Cl saturated aqueous solution. The solvent was evaporated *in vacuo*. The product was isolated from the reaction mixture using flash chromatography (SiO_2 , hexane/chloroform/ethyl acetate, 2 : 4 : 1), and recrystallized from the hexane/acetone/THF mixture (2 : 1 : 1) to give 1,2-(bis(2-formyl-5-yl)pyridinyl)ethyne **2a** as a yellow solid in 62% yield. $^1\text{H-NMR}$ (CDCl_3 , 250 MHz, 298 K, 64 scan), δ ppm: 8.04 (d, 2H, $^3J = 8$ Hz, H-4), 8.33 (d, 2H, $^3J = 8$ Hz, H-3), 9.09 (s, 2H, H-6), 10.03 (s, 2H, $-\text{CHO}$). $^{13}\text{C-NMR}$ (CDCl_3 , 63 MHz, 298 K, 256 scan), δ ppm: 59.3 (C-7), 121.6 (C-4), 125.1 (C-5), 138.8 (C-3), 150.2 (C-2), 150.5 (C-6), 191.2 ($-\text{CHO}$). MS-FD (70 eV, CH_2Cl_2) m/z : 236.0 (M^+), MW calculated $\text{C}_{14}\text{H}_8\text{N}_2\text{O}_2$ (MW^+) 236.23.

Biphenyl-4,4'-dicarbaldehyde (3a). *n*-BuLi (10 mL, 1.6 M solution in hexane, 16 mmol) was charged into a flame-dried flask filled with argon through a septum. Dry TMEDA (2 mL, 0.013 mmol) was added. After stirring at room temperature for 15 minutes the mixture was cooled to -78 °C (dry ice/*i*-PrOH), and a solution of 4,4'-dibromo-biphenyl **14** (2 g, 6.4 mmol) in dry THF (20 mL) was added slowly dropwise within 30 min. The temperature was slightly increased to -50 °C, due to a dramatic decrease in the solubility of the starting substrate at a lower temperature, and kept at this level for 25 minutes. After that the

temperature was lowered again to $-78\text{ }^{\circ}\text{C}$, and dry dimethylformamide (1.25 mL, $d = 0.94\text{ g mL}^{-1}$, 16.1 mmol) was added. The temperature was kept constant for 1 h, and then it was allowed to increase slowly. The obtained dense mixture was decomposed with NH_4Cl saturated aqueous solution and extracted with diethyl ether ($3 \times 50\text{ mL}$). The combined organic extracts were dried over MgSO_4 , and the solvents were evaporated under reduced pressure. The orange residue was recrystallized from dimethylformamide/water (1:2), yielding 0.78 g (58%) of light-yellow dialdehyde **3a**. $^1\text{H NMR}$ (CDCl_3 , 250.13 MHz), δ ppm: 7.71–7.75 (d, 4H, $^3J = 8.0\text{ Hz}$, H-2), 7.92–7.95 (d, 4H, $^3J = 8.0\text{ Hz}$, H-3), 10.02 (s, 2H, $-\text{CHO}$). $^{13}\text{C-NMR}$ (CDCl_3 , 63 MHz, 298 K, 206 scan), δ ppm: 128.1 (C-1), 130.4 (C-2), 136 (C-3), 145.6 (C-4), 191.7 ($-\text{CHO}$). MS-FD (70 eV, CH_2Cl_2) m/z : 210.1 (M^+), MW calculated $\text{C}_{14}\text{H}_{10}\text{O}_2$ (MW^+) 210.1.

Bipyridine-2,2'-dicarbaldehyde (4a). A solution of dimethyl bipyridine **15** (1 g, 5.38 mmol, 1 eq.), NBS (2.49 g, 14 mmol, 2.6 eq.), and benzoyl peroxide (0.29 g, 1.2 mmol, 0.22 eq.) in CCl_4 (50 mL) was refluxed under argon for 14 h. The precipitated succinimide was removed from the hot mixture by filtration. The precipitate was washed with CCl_4 ($2 \times 10\text{ mL}$), and the combined CCl_4 extracts were evaporated *in vacuo*. The resulting yellowish solid containing 5,5'-bis(bromomethyl)-2,2'-bipyridine **16** (1 g, 2.95 mmol, 1 eq.) was refluxed with hexamethylenetetramine (1.65 g, 11.8 mmol, 4 eq.) in 100 mL of ethanol/water (1:1) for 60 h. The mixture was extracted with ethyl acetate/toluene (1:1) ($4 \times 50\text{ mL}$) to afford effective phase separation. The organic extracts were collected and dried over MgSO_4 . The filtrate was concentrated *in vacuo* to a volume of ca. 2 mL, placed on a column with silica, and eluted with an ethyl acetate/hexane gradient solvent mixture (1:4, 1:3). The colorless fractions were collected and evaporated leading to product **4a** in 57% overall yield. $^1\text{H NMR}$ (CDCl_3 , 63 MHz, 298 K, 256 scan), δ ppm: 7.60–7.64 (d, 2H, $^3J = 8.02\text{ Hz}$, H-4), 7.94–7.98 (dd, 2H, $^3J = 8.02\text{ Hz}$, H-6), 8.76 (d, 2H, $^3J = 1.6\text{ Hz}$, H-3), 10.02 (s, 2H, $-\text{CHO}$). $^{13}\text{C-NMR}$ ($\text{THF}-d^8$, 63 MHz, 298 K, 338 scan), δ ppm: 121.3 (C-3), 127.6 (C-5), 129.4 (C-4), 131.9 (C-6), 136.4 (C-2), 189.7 ($-\text{CHO}$). MS-FD (70 eV, CH_2Cl_2) m/z : 211.6 (M^+), MW calculated $\text{C}_{14}\text{H}_{10}\text{O}_2$ (MW^+) 212.1.

B1. General synthesis of the 4,4,5,5-tetramethylimidazolidine-1,3-diol precursors 1–5b. A suspension of BHA (1.1 eq. for each aldehyde group) and an aldehyde (1.0 eq.) in toluene (5 mL/1 mmol) was carefully deaerated by purging with argon for ~ 20 –25 minutes. The flask was provided with a condenser equipped with an argon balloon, and placed in an oil bath. The mixture was heated under argon near reflux for 2–18 h. The progress of the reaction was monitored by TLC (SiO_2 , hexane/ethyl acetate or dichloromethane with 5% of methanol). After the process was complete and the flask was cooled down to room temperature, the precipitate (white or yellowish) was filtered off, washed with toluene ($2 \times 10\text{ mL}$) and heptane ($1 \times 10\text{ mL}$), and dried in air. The so-obtained derivatives were used further without additional purification.

B2. A solution containing BHA (1.3 eq. for each aldehyde group) and an aldehyde (1.0 eq.) in absolute deaerated methanol (10 mL/1 mmol) was stirred at room temperature for 12–72 h. The formed precipitate was filtered off, washed with cold ($\sim 5\text{ }^{\circ}\text{C}$)

methanol and dried in air. The product was used for the next step without additional purification.

2,2'-(2,2'-(Ethyne-1,2-diyl)bis(pyridine-2,5-diyl))bis(4,4,5,5-tetramethylimidazolidine-1,3-diol) (1b). Following protocol B1 starting from dipyridinedialdehyde **1a** (0.25 g, 1.1 mmol) was converted into the corresponding imidazolidine derivative **1b** in 4 h. Product **1b** was obtained as a pale-yellow powder in 80% yield (0.42 g). $^1\text{H-NMR}$ ($(\text{CD}_3)_2\text{SO}$, 250 MHz, 298 K, 128 scan), δ ppm: 1.08 (d, 24H, CH_3), 4.62 (s, H-7), 7.72 (d, 2H, $^3J = 8\text{ Hz}$, H-3), 7.92 (dd, 2H, $^3J = 8\text{ Hz}$, H-4), 8.69 (s, 2H, H-6). $^{13}\text{C-NMR}$ ($(\text{CD}_3)_2\text{SO}$, 75 MHz, 298 K, 18904 scan), δ ppm: 17.6, 24.5 (CH_3), 66.7 ($\text{C}-\text{CH}_3$), 88.1 (C-7), 127.2 (C-3), 136.8 (C-4), 137.9 (C-5), 140.9 (C-2), 150.7 (C-6). MS-FD (70 eV, CH_2Cl_2) m/z : 496.4 (M^+), MW calculated $\text{C}_{26}\text{H}_{36}\text{N}_6\text{O}_4$ (MW^+) 496.60.

2,2'-(5,5'-(Ethyne-1,2-diyl)bis(pyridine-2,5-diyl))bis(4,4,5,5-tetramethylimidazolidine-1,3-diol) (2b). Bisimidazolidine-diol **2b** was synthesized in 67% yield from dialdehyde **2a** (0.1 g, 0.4 mmol) and BHA (0.14 g, 0.96 mmol) following general protocol B2. $^1\text{H-NMR}$ ($(\text{CD}_3)_2\text{SO}$, 250 MHz, 298K, 16 scan), δ ppm: 1.09 (s, 24H, CH_3), 4.69 (s, H-7), 7.68 (d, 2H, $^3J = 8\text{ Hz}$, H-3), 8.02 (dd, 2H, $^3J = 8\text{ Hz}$, H-4), 8.71 (d, 2H, H-6). MS-FD (70 eV, CH_2Cl_2) m/z : 496.1 (M^+), MW calculated $\text{C}_{26}\text{H}_{36}\text{N}_6\text{O}_4$ (MW^+) 496.60.

2,2'-(Biphenyl-4,4'-diyl)bis(4,4,5,5-tetramethylimidazolidine-1,3-diol) (3b). Compound **3b** was synthesized in accordance with general procedure B1 from biphenyl-4,4'-dicarbaldehyde **3a** (0.305 g, 1.5 mmol) and BHA (0.64 g, 4.3 mmol) in quantitative yield (0.65 g, 95%). $^1\text{H NMR}$ ($(\text{CD}_3)_2\text{SO}$, 250.13 MHz), δ ppm: 1.11 (s, 12H, CH_3), 1.13 (s, 12H, CH_3), 4.59 (s, 2H, $\text{N}-\text{CH}-\text{N}$), 7.42–7.76 (m, 8H, ArH), 7.83 (s, 4H, $-\text{OH}$). $^{13}\text{C NMR}$ ($(\text{CD}_3)_2\text{SO}$, 63 MHz, 298 K, 256 scan), δ ppm: 17.6, 24.8 (CH_3), 66.5 ($\text{C}-\text{CH}_3$), 90.4 ($\text{N}-\text{CH}-\text{N}$), 126.3, 129.5 (CH_{Ar}), 139.8, 141.4 (C_{Ar}). MS-FD (70 eV, CH_2Cl_2) m/z : 470.1 (M^+), MW calculated $\text{C}_{26}\text{H}_{30}\text{N}_6\text{O}_4$ (MW^+) 470.60.

2,2'-(Bipyridine-1,1'-diyl)bis(4,4,5,5-tetramethylimidazolidine-1,3-diol) (4b). Bipyridine imidazolidine **4b** was synthesized following methodology B1. Thus, **4b** was obtained from the reaction between bipyridine-2,2'-dicarbaldehyde **4a** (0.15 g, 0.71 mmol) and BHA (0.28 g, 1.85 mmol) in 88% yield (0.30 g). $^1\text{H NMR}$ ($(\text{CD}_3)_2\text{SO}$, 250.13 MHz), δ ppm: 0.84–0.87 (d, 24H, CH_3), 4.40 (s, 2H, $\text{N}-\text{CH}-\text{N}$), 7.68 (s, 4H, $-\text{OH}$), 7.73–7.77 (d, 2H, ArH), 8.12–8.15 (d, 2H, ArH), 8.48 (s, 2H, ArH). $^{13}\text{C NMR}$ ($(\text{CD}_3)_2\text{SO}$, 63 MHz, 298 K, 256 scan), δ ppm: 17.3, 20.8 (CH_3), 66.3 ($\text{C}-\text{CH}_3$), 87.9 ($\text{N}-\text{CH}-\text{N}$), 125.8, 127.9, 131.9 (CH_{Ar}), 137.4, 146.5 (C_{Ar}). MS-FD (70 eV, CH_2Cl_2) m/z : 471.8 (M^+), MW calculated $\text{C}_{26}\text{H}_{30}\text{N}_6\text{O}_4$ (MW^+) 472.28.

2-(4-{2-[4-(1,3-Dihydroxy-4,4,5,5-tetramethyl-imidazolidine-2-yl)phenyl]ethynyl}phenyl)-4,4,5,5-tetramethyl-imidazolidine-1,3-diol (5b). Following general method B1 from 0.45 g (1.94 mmol) of the tolane dialdehyde **5a**¹¹ 0.94 g of pale-yellow bisimidazolidine **5b** was synthesized (98% yield). $^1\text{H-NMR}$ ($(\text{CD}_3)_2\text{SO}$, 250 MHz, 298 K, 105 scan), δ ppm: 1.05, 1.09 (both s 12 H, $-\text{CH}_3$), 4.54 (s, 2H, $\text{C}_{\text{imid-2}}$), 7.53 (w.s, 8H, Ar-H), 7.84 (w.s, 4H, $-\text{N}-\text{OH}$).

[§] The $^{13}\text{C-NMR}$ spectrum of **2b** was not obtained, as the sample appeared to be unstable in DMSO and began to oxidize in the NMR tube upon measurement.

^{13}C -NMR ($(\text{CD}_3)_2\text{SO}$, 63 MHz, 298 K, 256 scan), δ ppm: 17.4, 24.5 ($-\text{CH}_3$), 66.4 ($\text{C}_{\text{imid-4}}$, $\text{C}_{\text{imid-5}}$), 88.2 ($-\text{C}\equiv\text{C}-$), 90.1 ($\text{C}_{\text{imid-2}}$), 121.6 (Ar-C), 128.2, 131.0 (ArC-H), 143.5 (Ar-C). MS-FD (70 eV, $(\text{CD}_3)_2\text{SO}$) m/z : 494.293 (M^+), MW calculated $\text{C}_{28}\text{H}_{38}\text{N}_4\text{O}_4$ (MW^+) 494.291.

C. General procedure for the oxidation of 4,4,5,5-tetramethylimidazolidine-1,3-diol derivatives to nitronyl nitroxides.

A suspension of 4,4,5,5-tetramethylimidazolidine-1,3-diol (1 mmol) in a $\text{H}_2\text{O}/\text{CH}_2\text{Cl}_2$ (1 : 2) mixture (~ 50 mL) was cooled down to $0-5^\circ\text{C}$ using an ice bath. To that mixture a 5% aqueous solution of NaIO_4 (0.8 eq.) was added dropwise. The progress of the reaction was monitored by TLC (SiO_2 , hexane/ethyl acetate or dichloromethane with 5% methanol). After the reaction was complete (0.5–3 h), a dark-blue organic layer was separated. The aqueous layer was extracted with dichloromethane (3×25 mL). The combined organic extracts were additionally washed with water (2×30 mL), brine (1×50 mL), and dried over MgSO_4 (in some cases – Na_2SO_4). The residue after filtration was reduced to a volume of 2 mL, and purified on a chromatographic column (SiO_2 , hexane/ethyl acetate or $\text{CH}_2\text{Cl}_2/\text{MeOH}$).

2,2'-(2,2'-(Ethyne-1,2-diyl)bis(pyridine-2,5-diyl))bis(4,4,5,5-tetramethyl-4H,5H-imidazoline-1-oxyl-3-oxo) (1c). Procedure C and subsequent purification through a short flash-column (SiO_2 , hexane/ethyl acetate, 1 : 3) afforded 54 mg of the bluish crystals of **1c** (13%). M.p.: $219-220^\circ\text{C}$. UV-Vis (CHCl_3) λ/nm (ϵ , $\text{mol}^{-1}\text{cm}^{-1}$): 612 (808), 344 (55 554); (toluene) λ/nm (ϵ , $\text{mol}^{-1}\text{cm}^{-1}$) 623 (483), 345 (50402). FT-IR (solid; ν/cm^{-1}): 3108, 3072, 2986, 2939 (s, $\text{Py}_{\text{C-H}}$ stretching), 2144 (w, $\text{C}\equiv\text{C}$), 1734 (m, $\text{C}=\text{O}$), 1583 (s, $\text{Py}_{\text{C=C}}$ stretching), 1549 (s, $\text{C}=\text{N}_{\text{imid}}$), 1347 (s, N-O). Elemental analysis: C 62.7; H 5.96; N 17.02; calculated for $\text{C}_{26}\text{H}_{30}\text{N}_6\text{O}_4$: C 63.66; H 6.16; N 17.13.

2,2'-(5,5'-(Ethyne-1,2-diyl)bis(pyridine-2,5-diyl))bis(4,4,5,5-tetramethyl-4H,5H-imidazoline-1-oxyl-3-oxo) (2c). To a magnetically stirred solution of imidazolidine **2b** (0.133 g, 0.27 mmol) in absolute methanol (3 mL) an excess of MnO_2 (0.35 g, 4 mmol, 15 equivalents with respect to **2b**) was added. The process was monitored by TLC to avoid overoxidation, and an imino nitroxide radical formed. After the reaction was complete MnO_2 was filtered off and methanol was evaporated. The radical was purified using thin-plate chromatography (SiO_2 , chloroform/ethyl acetate, 2 : 1). After evaporation of the solvent blue crystals were obtained in 34% total yield. M.p.: $236-239^\circ\text{C}$. UV-Vis (CHCl_3) λ/nm (ϵ , $\text{mol}^{-1}\text{cm}^{-1}$): 591 (503), 341 (38 929). FT-IR (powder, ν/cm^{-1}): 3048, 2985, 2933, 2868 (s, $\text{Py}_{\text{C-H}}$ stretching), 2141 (w, $\text{C}\equiv\text{C}$), 1733 (m, $\text{C}=\text{O}$), 1588 (m, $\text{Py}_{\text{C=C}}$ stretching), 1560 (s, $\text{C}=\text{N}_{\text{imid}}$), 1360 (s, N-O). Elemental analysis: C 63.1; H 6.22; N 16.62; calculated for $\text{C}_{26}\text{H}_{30}\text{N}_6\text{O}_4$: C 63.66; H 6.16; N 17.13.

D. General procedure for the oxidation of 4,4,5,5-tetramethylimidazolidine-1,3-diol derivatives to imino nitroxides.

To a magnetically stirred solution of imidazolidine (1 mmol) in nitromethane (12 mL) MnO_2 (14 mmol) was added. After ~ 35 minutes of stirring at room temperature the oxidant was filtered off and washed carefully with small portions of ethyl acetate on a filter. The filtrate was diluted with toluene (12 mL) and concentrated to a volume of ca. 2 mL *in vacuo*. The residue was placed on a column wetted with toluene, and eluted with an ethyl acetate/hexane mixture.

2,2'-(2,2'-(Ethyne-1,2-diyl)bis(pyridine-2,5-diyl))bis(4,4,5,5-tetramethyl-4H,5H-imidazoline-1-oxyl) (1d). Compound **1d** was synthesized as described in protocol D from imidazolidine **1b** (0.47g, 0.95 mmol) using MnO_2 (1.23 g, 14.1 mmol) in 61% yield (250 mg). M.p.: compound decomposed at 195°C . UV-Vis (toluene) λ/nm (ϵ , $\text{mol}^{-1}\text{cm}^{-1}$): 467 (944), 326 (35 207). FT-IR (powder, ν/cm^{-1}): 3067, 2969, 2924 (s, $\text{Py}_{\text{C-H}}$ stretching), 2136 (w, $\text{C}\equiv\text{C}$), 1591 (s, $\text{Py}_{\text{C=C}}$ stretching), 1555 (s, $\text{C}=\text{N}_{\text{imid}}$), 1368 (m, N-O). Elemental analysis: C 67.6; H 6.43; N 18.07; calculated for $\text{C}_{26}\text{H}_{30}\text{N}_6\text{O}_2$: C 68.10; H 6.59; N 18.30.

2,2'-(Biphenyl-4,4'-diyl)bis(4,4,5,5-tetramethylimidazolidine-1-oxyl) (3d). Oxidation of precursor **3b** (0.3 g, 0.64 mmol) with excess of MnO_2 (0.83 g, 9.5 mmol) according to methodology D was complete in 20 minutes. Radical **3d** was purified on a chromatographic column with a hexane/ethyl acetate gradient solvent mixture (5 : 1, 3 : 1). The yield of orange crystals of **3d** was 0.14 g (47%). M.p.: $248.5-250^\circ\text{C}$. UV-Vis (CHCl_3) λ/nm (ϵ , $\text{mol}^{-1}\text{cm}^{-1}$): 461 (1090), 486 (1016). FT-IR (powder, ν/cm^{-1}): 3069, 2973, 2926, 2862 (s, Ph-C-H stretching), 1611 (s, Ph C=C stretching), 1567 (w, $\text{C}=\text{N}$), 1364 (s, N-O). Elemental analysis: C 71.86; H 7.32; N 12.66; calculated for $\text{C}_{26}\text{H}_{32}\text{N}_4\text{O}_2$: C 72.19; H 7.46; N 12.95.

2,2'-(Bipyridine-1,1'-diyl)bis(4,4,5,5-tetramethylimidazolidine-1-oxyl) (4d). The titled biradical **4d** was achieved using a procedure similar to the one described above in 44% yield. M.p.: compound began to decompose at 253°C . UV-Vis (CHCl_3) λ/nm (ϵ , $\text{mol}^{-1}\text{cm}^{-1}$): 448 (625), 476 (548). FT-IR (powder, ν/cm^{-1}): 3087, 3043, 2981 (s, $\text{Py}_{\text{C-H}}$ stretching), 1603 (s, $\text{Py}_{\text{C=C}}$ stretching), 1562 (s, $\text{C}=\text{N}_{\text{imid}}$), 1366 (s, N-O). Elemental analysis: C 65.36; H 7.02; N 19.11; calculated for $\text{C}_{24}\text{H}_{30}\text{N}_6\text{O}_2$: C 66.34; H 6.96; N 19.34.

2-(4-{2-[4-(1-Oxyl-4,4,5,5-tetramethyl-4H,5H-imidazolin-2-yl)-phenyl]-ethynyl}phenyl)-4,4,5,5-tetramethyl-imidazoline-1-oxyl-3-oxo (5d). Compound **5d** was synthesized from precursor **5b** (0.27 g, 0.55 mmol) employing an excess of MnO_2 (0.7 g, 8.05 mmol) as described in more detail in general procedure C. Isolation of product **5d** using a chromatographic column with silica gel and a hexane/ethyl acetate (3 : 2) eluent mixture afforded red crystals of **5d** in 58% total yield. M.p.: compound began decomposing above 195°C . UV-Vis (toluene) λ/nm (ϵ , $\text{mol}^{-1}\text{cm}^{-1}$): 467 (944), 326 (35 207). FT-IR (powder, ν/cm^{-1}): 3067, 2969, 2924 (s, $\text{Py}_{\text{C-H}}$ stretching), 2136 (w, $\text{C}\equiv\text{C}$), 1591 (s, $\text{Py}_{\text{C=C}}$ stretching), 1555 (s, $\text{C}=\text{N}_{\text{imid}}$), 1368 (m, N-O). Elemental analysis: C 73.15; H 6.76; N 12.11; calculated for $\text{C}_{28}\text{H}_{32}\text{N}_4\text{O}_2$: C 73.66; H 7.06; N 12.27.

Conclusion

We have demonstrated that the synthesis and study of structurally similar compounds exhibiting different magnetic behaviors provide a reasonable approach for understanding the relationship between the substituents in the aromatic ring and the intramolecular exchange constant J_{intra} . Unfortunately, the magnetic interactions based on structural peculiarities are difficult to predict as their strength strongly depends on the relative orientation

between the interacting magnetic orbitals. Here, the torsion angles θ have crucial impacts on the overall π -conjugation in the nitroxide biradical systems. The latter in turn is responsible for the efficient communication between the nitroxide fragments. The crystal structure analysis shows that the synthesized biradicals are planar with relatively small torsions between the radical fragments and the aromatic bridges (with an exception in the case of derivative **2c**). These are the essential prerequisites for obtaining a weak intramolecular coupling. A rapid increase of the torsion hinders the conjugation within the biradical system **2c**, decreasing the intramolecular exchange interactions within the molecule. This structural feature causes an enhancement of the intermolecular coupling within **2c**. As a result, an unprecedentedly high value of the coupling constant is observed in NN biradical **2c**. This work illustrates the difficulties in the design and prediction of a target structure, and the need for an experimental proof.

Magnetic measurements, carried out on single-crystalline samples, confirmed that for biradicals **1c**, **1d**, **3d**, **4d** and **5d**, weak antiferromagnetic intramolecular interactions are predominant. According to the magnetic characterization studied π -bridged nitroxides possess a moderate intra-dimer coupling in the range -2 to -6 K as derived from the fits based on an isolated dimer model. Furthermore, magnetic measurements and their interpretation revealed that NN biradical **2c** exhibits surprisingly strong antiferromagnetic interactions, owing to the short (~ 3.5 Å) interdimer interaction. IN biradical **5d** features a field-induced ordered phase assigned to 3D interdimer couplings, which accounts for a description in terms of a BEC of triplons.

In summary, we have found promising candidates in the quest for purely organic molecular magnets and crystalline networks with higher ordering.
