Minimising conformational bias in fluoroprolines through vicinal difluorination†‡

Gert-Jan Hofman, Emile Ottoy, Mark E. Light, Bruno Kieffer, Ilya Kuprov, Jose C. Martins, Davy Sinnaeve and Bruno Linclau

Monofluorination at the proline 4-position results in conformational effects, which is exploited for a range of applications. However, this conformational distortion is a hindrance when the natural proline conformation is important. Here we introduce (3S,4R)-3,4-difluoroproline, in which the individual fluorine atoms instil opposite conformational effects, as a suitable probe for fluorine NMR studies.

Proline is the only proteinogenic amino acid with a secondary amino group, resulting in the cis-peptide bond (Xaa–Pro) being significantly populated (Fig. 1a).1 The proline amino group is part of a pyrrolidine ring, and its five-membered ring pucker is thus closely connected with the backbone $\phi$-dihedral angle. In addition, its cyclic nature inherently restricts this dihedral angle such that it enhances the importance of $n \rightarrow \pi^*$ interactions between subsequent carbonyl groups in peptides. This in turn has further implications for peptide conformation and influences the Xaa-Pro cis:trans ratio.1,2 These peculiar chemical features result in specific conformational and dynamical properties that are central to a number of biological mechanisms behind protein folding, protein aggregation or protein–protein interactions.3 The existence of peptidyl-prolyl cis-trans isomerases, a class of enzymes able to accelerate proline cis-trans isomerization, highlights the functional importance of this dynamical property in biology.4 Furthermore, post-translational modifications of the pyrrolidine ring by hydroxylation confer mechanical properties to proline-rich proteins such as collagen by further enhancing these $n \rightarrow \pi^*$ interactions.4 Moreover, post-translational modifications of the pyrrolidine ring by hydroxylation confer mechanical properties to proline-rich proteins such as collagen by further enhancing these $n \rightarrow \pi^*$ interactions.4

Incorporation of a fluorine atom at the proline 4- (or $\gamma$-) position strongly affects both its dynamical and conformational properties. Because of the highly polar C–F bond, a destabilisation of the planar charged amide resonance structures results, which manifests itself in an increased amide isomerisation rate. Ring pucker is affected through the gauche effect, which is a favourable $\sigma_{\text{C-H}} \rightarrow \sigma_{\text{C-F}}^*$ hyperconjugation interaction.5 This stereoelectronic effect requires the C–H and C–F bonds to be antiperiplanar, and the stereogenicity of the fluorine substituent thus leads to one of the two puckers being favoured (Fig. 1a).1 Furthermore, C–F introduction affects the overall dipole moment, which also influences conformational stabilities (with a strong solvent effect).6

$N$-Acylated proline esters such as 1–4 (Fig. 1b) are typical models to investigate the influence of fluorination on proline conformation.7 In a landmark study, Raines and Markley demonstrated, through NMR studies in 1,4-dioxane, that the exo-pucker is dominant in the (4R)-fluoroproline derivative 1 (75% population for the trans-isomer), while the endo-pucker is the most populated one for the 4S-isomer.2,7 Originally investigated for its effect on collagen stability,8 proline fluorination is now applied for a variety of purposes in the biosciences.
Fluorinated amino acids are of interest for biological \(^{19}\text{F}\) NMR applications, due to its high intrinsic sensitivity, its increased sensitivity to chemical exchange processes due to the broad chemical shift range, and the absence of background signals in biological fluids.\(^{10-11}\) Also, \(^{19}\text{F}\) labelling of single residues in a peptide or protein can afford easy access to site-specific information. Given the pivotal role of prolines in protein folding, stability and binding, and the biological importance of interactions with proline-rich motifs in signalling proteins,\(^{3}\) prolines would be a judicious choice to introduce a \(^{19}\text{F}\) reporter. Yet, while fluoropropines have been a much-used tool to study peptide/protein structure and dynamics, or interactions between peptides and receptors,\(^{3,8,9}\) their potential use as \(^{19}\text{F}\) NMR probes has, to the best of our knowledge, never been exploited.

In many cases, the conformational bias caused by the common singly fluorinated prolines is a hindrance for biological \(^{19}\text{F}\) NMR purposes, as it distorts the natural proline pucker conformation and/or amide cis-trans equilibrium and thus the properties of the system under study. Instead, for this purpose, fluorinated analogues in which two fluorines are introduced in such positions as to offset each other's conformational bias would be of more interest. For example, by combining the 4S and 4R-fluoro motif to give 4,4-difluropropoline derivatives (e.g. 5, Fig. 2), their respective stereoelectronic effects influencing pucker are expected to cancel out.\(^{1,3,13}\) While a detailed conformational analysis of 4,4-difluropropoline is yet to be published,\(^{1}\) initial analysis indicated that the exo- and endo-puckers of 4,4-difluropropoline are of similar energy, and that its preorganisational capacity is close to that of proline.\(^{3,14}\) However, a CF\(_2\)-group in which the two fluorine atoms are diastereotopic is not an ideal \(^{19}\text{F}\) NMR reporter group because of the very large geminal F–F coupling (>200 Hz). This leads to severe \(J\)-modulation distortions in any NMR experiment involving, for instance, spin echoes, which is a key problem. Furthermore, since the fluorines typically have relatively close chemical shifts, strong second order effects are present, which complicate spectral interpretation. In addition, when introducing multiple fluoropropoline probes, especially in similar environments (i.e. low-complexity peptide sequences such as polyprolines), the availability of a larger set of fluoropropoline analogues with minimal conformational bias is desirable to prevent spectral overlap.

We wished to investigate the extent of compensating conformational bias in the proline ring by vicinal introduction at different ring carbons. For this, proline positions 3 and 4 are the most practical. Such analogues feature vicinal instead of geminal \(^{19}\text{F}\text{–}^{19}\text{F}\) coupling, with \(J_{\text{F–F}} \propto \frac{1}{3}\) in addition, CHF groups have very different \(^{19}\text{F}\) chemical shift values than CF\(_2\) groups. This leads to 6 and 7 as analogues of interest (Fig. 2). There is some precedent for these structures: syntheses of the (3R,4S)-difluoropropoline motif,\(^{15}\) as in 6, and of the (3R,4R)-difluoropropoline (not shown) have been reported. Unfortunately, many synthetic steps were required to convert 3,4-dehydropropoline to Cbz-protected (3R,4S)-3,4-difluoro-L-proline and 3-deoxy-3-fluoro-1,2,5,6-di-O-isopropylideneglucofuranose to N-benzyl protected (3R,4R)-3,4-difluoro-L-proline.\(^{16}\)

Here we report a short synthesis of 7 from (4R)-hydroxyproline, as well as NMR studies (amide cis:trans ratio and amide isomerisation rates) and preliminary theoretical calculations (ring pucker). The results are compared to the equivalent data of the 4,4-difluorinated derivative 5.\(^{14}\) Given 5 can be regarded as a combination of the 4R- and 4S-fluoropropines 1 and 2, and the 3S,4R-difluoropropoline as a combination of the 3R- and 4S-fluoropropines 2 and 3, the corresponding conformational data of 1–3, all of which were synthesised using described methodology,\(^{17}\) were also obtained.

The synthesis of 7 is shown in Scheme 1, and employs a direct deoxyfluorination approach from the known\(^{18}\) 3,4-diol, which was obtained from a suitably protected 3,4-dehydropropoline. Marson has shown that bis-triflation of \(N\)-allylated trans-3,4-dihydroxyproline, followed by TBAF treatment led to trans-3,4-difluorohydroxyproline with inversion of configuration in excellent yields.\(^{19}\) Although the methyl ester and \(N\)-acetyl groups present in 7 could have been introduced from the start, benzyl ester and Boc amine protection was chosen in order to make the process relevant for the synthesis of suitable peptide synthesis building blocks. Given 3,4-dehydropropoline is expensive, cheap (4R)-hydroxypropoline was employed, which was protected to give known\(^{20,21}\) 8 (not shown). Elimination of 4-hydroxypropoline's hydroxyl group is typically achieved via a two-step procedure involving alcohol activation, leading to a mixture of 3,4- and 4,5-alkene isomers.\(^{18,22}\) Pleasingly, it was found that the one-pot Grieco elimination procedure\(^{23}\) starting from 8 gave the desired alkene 9 in excellent (10:1) selectivity. Dihydroxylation of 3,4-dehydropropoline with OsO\(_4\) has been reported to form the all-cis-diol isomer in small quantities.\(^{16}\) However, with potassium osmate (0.3 mol%), the \(trans\)-diol obtained is as the only observable isomer.\(^{22b}\) Direct conversion of the 3,4-diol to the required 3,4-difluoro motif was best achieved with nonafluorobutanesulfonyl fluoride (NFF) in combination with a triphenylfluorosilicate salt,\(^{24}\) which led to 11 as the only 3,4-difluorinated stereomer in 24% yield. The enol

![Fig. 2 Proposed difluorinated \(\alpha\)-prolines featuring compensating conformational bias towards proline pucker.](image-url)
sulfonate 12 was isolated in equal amounts, presumably through fluoride mediated E2 elimination of the corresponding bis-nonaflate intermediate. Only one regioisomer was isolated, which suggests that the bis-nonaflate intermediate preferentially adopted a C⁵-exo conformation, resulting in antiperiplanar disposition between the C₃–H and C₄–ONf bonds allowing for a smooth E2 reaction. Given this process essentially involves two separate deoxofluorination reactions, the obtained yield was deemed acceptable, as gram-scale quantities of 11 could be obtained. Finally, the protecting groups were replaced to give the 3,4-difluorinated model 7.

Unambiguous assignment of the relative stereochemistry proving inversion of configuration in the fluorination step could be obtained by X-ray crystallographic analysis of 11 (Fig. 3), which crystallised in a perfect C⁵-exo pucker.§

Despite the expected acceleration of the cis–trans isomerisation rate, the exchange remains slow on the NMR time scale and both amide rotamers of 5 and 7 are always separately visible in the ¹H and ¹⁹F NMR spectra. The difference in ¹⁹F chemical shift resonances of the cis rotamers is larger than that of the trans rotamers, both for 5 and 7 (Table 1). As expected the J_{F–F} values for 5 are much larger than these of 7; the close chemical shifts of the fluorine atoms of trans-5 result in a roofed set of doublets (upon ¹H decoupling).

Next, the conformational properties of 5 and 7 were determined, and compared with the non-fluorinated N-acetylated proline methyl ester, the 4,4-difluorinated derivative 5, and the monofluorinated prolines 1-3 (Table 2). The cis : trans ratio was measured with NMR for all compounds in CDCl₃ and D₂O. The ratios of both 5 and 7 in chloroform and water are quite similar to those of Ac-Pro-OME, clearly cancelling out the marked biases seen in their respective monofluorinated progenitors.

![Fig. 3 X-ray structure of 11 (Bn and tent-Bu group removed for clarity).](image)

The trans-isomer appears in both chloroform and water slightly morefavoured in 7 than in 5. Next, the kinetic rate constants of cis–trans isomerisation k_{cis-trans} and k_{trans-cis} were determined in D₂O by 2D ¹H–¹H or ¹⁹F–¹⁹F EXSY for 3, 5 and 7, while for Ac-Pro-OME, 1 and 2, values were calculated based on results reported by Renner et al.¹¹

Since k_{cis-trans} and k_{trans-cis} depend on the cis : trans ratios, we define their sum k_ex in order to compare isomerization kinetics between the different compounds. Clearly, every fluorinated compound shows accelerated isomerization kinetics compared to proline. When comparing the monofluorinated compounds, there are marked differences depending on the substitution patterns, even between 1 and 2, showing that inductive effects alone do not explain the change in rate constant. Both doubly fluorinated compounds 5 and 7 show a further increase in isomerization kinetics, and turn out to have very similar rate constants. Interestingly, while 5 shows faster kinetics than its monofluorinated progenitors 1 and 2, 7 unexpectedly has a slightly lower k_ex value than 3 (though markedly higher than 2).

Finally, the preference of the five-membered ring pucker was assessed by DFT, using the M06 functional with cc-pVDZ basis set and chloroform or water as implicit solvents (Table 2). It is clear that the monofluorinated compounds 1, 2 and 3 alter the pucker preference profoundly, while doubly fluorinated 5 and 7 display pucker ratios much more similar to the Pro model compound. In chloroform, 7 deviates more from Pro compared to 5, with higher preference for the exo-pucker. In water, the limited deviations to Pro for both 5 and 7 are similar and in opposite sense compared to the trans form.

In conclusion, we find that 3⁵,4⁴-difluoro proline, with a vicinal cis-difluromotif, is a proline analogue featuring minimal conformational bias with respect to the cis–trans rotamers and ring pucker thanks to the offsetting stereoelectronic effects instilled by the individual fluorine atoms. While the 4,4-difluoroproline variant also displays such characteristics, the 3,4-difluoroproline is superior as a fluorinated proline marker for¹⁹F spectroscopic studies of natural proline containing peptides and proteins due to the much more suitable NMR properties. Furthermore, we suggest that the very different chemical shifts of the 3,4- and 4,4-difluoroprolines offers opportunities for multi-proline labelling in peptides. The short, gram-scale synthesis assures convenient access to the 3⁵,4⁴-difluoro isomer, and the improvements for the hydroxyproline elimination and 3,4-dehydroproline dihydroxylation reactions, will be useful for synthetic proline chemistry. The 3⁵,4⁴-difluoroproline analogue is a valuable addition for applications of fluorinated prolines in medicinal chemistry and structural biology. Applications of these prolines in¹⁹F NMR structural studies are in progress.

We thank the University of Southampton for funding. The Research Foundation – Flanders (FWO) is indebted for a research project to J. C. M. and D. S. (3G011015), PhD and postdoctoral fellowships to E. O. and D. S., and staff exchange funding (FWO-WOG Multimar). The EPSRC is thanked for a partial PhD grant to G.-J. H. (EPSRC-DTG EP/M50662X/1) and instrument funding (core capability EP/K039466/1).
