Rational design of new cyclic analogues of the antimicrobial lipopeptide tridecaptin A₁†

 Ross D. Ballantine, ^a Yong-Xin Li, ^b Pei-Yuan Qian^b and
Stephen A. Cochrane ^{*a}

Non-ribosomal peptides (NRPs) are a rich source of antibiotic candidates. However, it was recently discovered that resistance to NRPs can be mediated by D-stereoselective peptidases. The tridecaptins, a class of NRPs that selectively target Gram-negative bacteria, are degraded by the D-peptidase TriF. Through analysis of a solution NMR structure of tridecaptin A₁, we have rationally synthesized new cyclic tridecaptin analogues that retain strong antimicrobial activity and are resistant to TriF.

Antimicrobial resistance is a major global concern. It has been estimated that if the current rise in infections resulting from multidrug resistant bacteria is not subdued, by 2050 they will cause more deaths than cancer.¹ Due to the inherent ability of bacteria to develop resistance mechanisms, new antimicrobial compounds and targets will always be needed.² In recent years, there has been a worrying lack of new antibiotics that target Gram-negative bacteria.³ These pathogens have an extra layer of protection in the form of the outer-membrane, which precludes the entry of many large-scaffold antibiotics.⁴ Several of the Gram-negative-targeting antibiotics currently undergoing clinical trials are derivatives of known classes (*e.g.* β-lactams/β-lactamase inhibitors) and could therefore be more susceptible to resistance development.⁵ Non-ribosomal peptides (NRPs) are becoming increasingly important in the fight against MDR bacteria, with many new classes being discovered in recent years.⁶ D-Amino acid-containing NRPs (DNRPs) are often resistant to peptidases as the vast majority of peptidases only cleave L-peptide bonds. However, recent studies have identified the widespread distribution of D-stereoselective peptidases. For example, the D-peptidase BogQ can degrade the DNRPs bacitracin, rampoplanin and daptomycin, all of which are clinically used antibiotics.

Therefore, D-peptidases could pose a major threat to the longevity of NRP antibiotics.⁷

The tridecaptins are a class of linear DNRPs isolated from *Bacillus* and *Paenibacillus* species.⁸ Tridecaptin A₁ (TriA₁) is the archetypical member of this class and shows strong activity against Gram-negative bacteria, including multidrug resistant (MDR) strains of *Escherichia coli*, *Klebsiella pneumoniae* and *Acinetobacter baumannii* (Fig. 1A).⁹ TriA₁ exerts its bactericidal effect by binding to lipid II on the inner-membrane and disrupting the proton-motive force.¹⁰ The interaction between TriA₁ and lipid II imbedded in dodecylphosphocholine (DPC) micelles was recently studied by NMR.¹⁰ In the absence of lipid II, TriA₁ adopts a tight hairpin-like amphiphilic structure, however a more open looped structure is adopted upon lipid II binding (Fig. 1B). Analysis of this structure suggests that the loop is stabilized by a π-stacking interaction between D-Trp5 and L-Phe9. A previously reported alanine scan of TriA₁ corroborates the importance of these residues, as substitution of either D-Trp5 or L-Phe9 significantly decreases antimicrobial activity.¹¹

The tridecaptins are attractive antibiotic candidates, owing to their selective activity against Gram-negative bacteria and ease of preparation by solid-phase peptide synthesis (SPPS). However, it was recently discovered that the tridecaptins are hydrolytically cleaved by the D-peptidase TriF at the amide bond between D-Trp5 and Ser6, rendering them inactive.⁷ Although this is likely a self-protection mechanism, similar resistance mechanisms could develop in more pathogenic bacteria, rendering these DNRPs inactive. Macrocyclization is often an effective strategy to improve the stability of peptides towards peptidases.¹² However, N to C cyclization, which is one of the most commonly used methods to cyclize peptides, is not appropriate for the tridecaptins. Firstly, they are N-acylated, making N to C cyclization more difficult. Secondly and most importantly, the lipid II-bound conformation of TriA₁ places the N- and C-termini far apart as it wraps around lipid II on the cell membrane (Fig. 1B). Given that D-Trp5 and L-Phe9 are in close proximity through a π-stacking interaction, and that D-Trp5 is cleaved by TriF, we rationalized that replacement of this π-stacking interaction with a covalent

Fig. 1 (A) Structure of TriA₁ with TriF cleavage site shown in red. (B) NMR solution structure of TriA₁ bound to lipid II (not shown) in DPC micelles (PDB ID: 2N5W). A π -stacking interaction that may stabilize the looped structure is shown.

linkage could impart resistance to TriF, as well as providing a new scaffold of macrocyclic peptides that specifically target Gram-negative bacteria. The generation of cyclic TriA₁ (cTriA₁) analogues cyclized between these positions would also corroborate the importance of the looped secondary structure in the mechanism of action of this peptide. Herein, we discuss our synthesis of novel cyclic TriA₁ analogues that retain strong antimicrobial activity and are resistant to the D-peptidase TriF.

Oct-TriA₁ (**1**) was first synthesized by Fmoc-SPPS and tested against a model Gram-negative (*Escherichia coli*) and Gram-positive (*Staphylococcus aureus*) indicator strain (Table 1). Replacement of the chiral lipid tail on TriA₁ with octanoic acid has no effect on antimicrobial activity, therefore N-terminal octanoylation was employed for all analogues.⁹ Consistent with previous reports, Oct-TriA₁ (**1**) showed potent activity against *E. coli* and weak activity against *S. aureus*. Our initial efforts to prepare cyclic TriA₁ (cTriA₁) analogues focused on replacing the D-Trp5-Phe9 π -stacking interaction with an alkene bridge using on-resin

ring-closing metathesis (RCM). Derksen and Vederas previously used this strategy to replace a disulfide in the antimicrobial peptide leucocin A.¹³ Oct-TriA₁-(5-D-Agl, 9-Agl) (**2**) was synthesized by SPPS, however, the full-length peptide proved refractory to on-resin RCM. We rationalized that the peptide might be aggregating, therefore we also attempted the cyclization at the nonapeptide stage of synthesis. However, this also failed. Further attempts involving increased catalyst loading, alternate solvents, increased reaction temperature or chaotropic salts¹³ were also unsuccessful. We postulated that extension of the alkene chains as S-allylcysteine (Sac) could facilitate cyclization, however exposure of Oct-TriA₁-(5-D-Sac, 9-Sac) (**3**) to RCM conditions failed to yield any cyclic product. Neither alkene-containing peptide showed antimicrobial activity $< 50 \mu\text{g mL}^{-1}$, suggesting that hydrophobic interactions are not sufficient to stabilize the active conformation of TriA₁. Previous studies have shown that not all peptides undergo RCM, with yields often highly dependent on peptide sequence.¹⁴ This situation often arises in peptides containing a large number of hydrophobic amino acids.¹⁵ Therefore, we believe that the significant hydrophobicity of the C-terminal region of Oct-TriA₁ causes aggregation on-resin that hinders the RCM reaction. This limitation could be overcome in solution using an aqueous/organic solvent mix, as Oct-TriA₁ is conformationally flexible in these solvent systems.¹¹ However, as the vast excess of chaotropic salts required makes purification difficult,¹⁶ we directed our efforts towards an alternative cyclization method (Scheme 1).

The cross-linking of cysteine residues is another method used to staple peptides,¹⁷ which has been used to prepare cell-penetrant inducers of autophagy¹⁸ and p53 inhibitors.¹⁹ In both studies the macrocycle ring size affected activity. Therefore, we directed our efforts towards the generation of cTriA₁ analogues with varying ring-sizes. Oct-TriA₁-(5-D-Cys, 9-Cys) (**4**) was first synthesized by SPPS. Next, disulfide **5**, the smallest possible macrocycle, was synthesized from dithiol **4** but showed no antimicrobial activity. Dithiol **4** was then cross-linked with different benzylic cross-linkers to yield Oct-cTriA₁ analogues **6–9**, which contain increasingly larger macrocyclic rings. Peptides **6–8**, wherein cysteines have been crosslinked with *o*-, *m*- and *p*-Xyl linkers respectively, retained strong activity against *E. coli* ($6.3 \mu\text{g mL}^{-1}$), although

Table 1 Antimicrobial activity of linear TriA₁ analogues

Peptide	Amino acid		MIC ^a	
	5	9	<i>E. coli</i> ^b	<i>S. aureus</i> ^c

Scheme 1 Synthesis of novel cyclic analogues of TriA₁. MIC = minimum inhibitory concentration. Determined by microbroth dilutions assays and experiments run in duplicate. Values are shown to two significant figures and reported in $\mu\text{g mL}^{-1}$. ^a Strain NCTC 12241. ^b Strain NCTC 10788. ^c Strain NCTC 9633. ^d Strain NCTC 13304. ^e Strain NCTC 5920.

none were active against *S. aureus*. Further ring expansion using a biphenyl linker yielded peptide **9**, however this peptide showed no activity at the highest concentrations tested ($50 \mu\text{g mL}^{-1}$). Encouraged by these results, we tested the activity of peptides **6–9** against more clinically significant Gram-negative bacteria, including *Klebsiella pneumoniae*, and the critical tier pathogens *Acinetobacter baumannii* and *Enterobacter cloacae*.²⁰ Gratifyingly, peptides **6–8** showed strong activity against all strains. Activity against *A. baumannii* NCTC 13304, which is a carbapenem resistant strain,²¹ is particularly promising as this is currently the WHO's No. 1 priority pathogen.²⁰ We next attempted to synthesize cTriA₁ analogues containing saturated hydrocarbon cross-links. Performing these reactions under the same conditions did not yield any cyclic product, with just linear starting material recovered. Increasing reaction temperatures thermally, or by microwave irradiation, lead to the formation of several side-products, including linear peptides in which one of the cysteine residues had been converted to dehydroalanine. This likely occurs through bisalkylation of a single Cys, followed by elimination of the resulting sulfonium. We therefore moved forward with TriA₁ analogues **1–9** to study their susceptibility to degradation by the D-peptidase TriF.

The D-stereoselective peptidase TriF is a membrane associated protein found in *Paenibacillus polymyxa* CICC 10580.⁷ TriF_{pep}, the soluble periplasmic peptidase domain of TriF, which lacks the signal peptide and four hydrophobic transmembrane helices, was expressed in *E. coli* BL21 cells as a C-terminal His₆-tag protein construct.⁷ TriA₁ analogues **1–9** were incubated with TriF_{pep} at 37 °C for 12 h and the reaction mixtures analysed by UPLC-MS. Both Oct-TriA₁ (**1**) and Oct-TriA₁(5-D-Sac, 9-Sac) (**3**) were degraded

Fig. 2 Liquid chromatography-mass spectrometry traces of *in vitro* assays of TriF_{pep} against Oct-TriA₁ (**1**, black peaks) and *o*-Xyl- (**6**, blue peaks), *m*-Xyl- (**7**, green peaks) and *p*-Xyl- (**8**, red peaks) crosslinked peptides. Standards (black line) without TriF_{pep} and experiments with TriF_{pep} (red line) are shown. Whereas Oct-TriA₁ is cleaved by TriF_{pep}, no corresponding cleavage was observed in TriF_{pep} treated **6–8**.

by TriF_{pep} (Fig. 2 and Fig. S1, ESI[†]), whereas Cys analogue **4** and cTriA₁ analogues **5–8** were completely resistant (Fig. 2). We were unable to test the stability of Oct-cTriA₁(biphenyl) (**9**) as it is insoluble in the TriF assay mixture. Although **4** and **5** are resistant to TriF, they also have negligible antimicrobial activity. In contrast, peptides **6–8**, which have been crosslinked with Xyl linkers, retain strong antimicrobial activity and are resistant to TriF. These analogues therefore represent a new scaffold of macrocyclic peptides with selective activity against Gram-negative bacteria. Furthermore, this work highlights the importance of the π -stacking interaction to TriA₁'s mechanism of action.

Improvements in the antimicrobial activity of the cTriA₁ analogues should be possible through further structure–activity relationship studies.

In conclusion, we have employed a rational design approach to generate new cyclic analogues of tridecaptin A₁ that are resistant to the D-peptidase TriF. Analysis of an NMR solution structure of TriA₁ identified a possible cyclization point between positions 5 and 9, which are in close proximity due to a π -stacking interaction. Substitution of D-Trp5 and L-Phe-9 with D-Cys and L-Cys respectively, followed by cross-linking with benzylic di-bromo linkers yielded cyclic TriA₁ analogues that retain selective activity against Gram-negative bacteria and are resistant to TriF. To the best of our knowledge, the replacement of π -stacking interactions with a covalent linkage to impart peptidase stability is a novel strategy. These structures constitute a new class of Gram-negative-targeting macrocyclic peptides and could be the basis for new antibiotic candidates.
