## Slow magnetic relaxation in a $\{\text{Co}^{\text{II}}\text{Co}_2^{\text{III}}\}$ complex containing a high magnetic anisotropy trigonal bipyramidal $\text{Co}^{\text{II}}$ centre†

Alexandra Collet,<sup>a</sup> Gavin A. Craig,<sup>†a</sup> María José Heras Ojea,<sup>§a</sup>  
Lakshmi Bhaskaran,<sup>b</sup> Claire Wilson,<sup>§a</sup> Stephen Hill<sup>§b</sup> and Mark Murrie<sup>§a\*</sup>

**We report a trinuclear mixed-valence  $\{\text{Co}^{\text{II}}\text{Co}_2^{\text{III}}\}$  complex, where the  $\text{Co}^{\text{II}}$  centre adopts a trigonal bipyramidal geometry, leading to a large, easy-plane magnetic anisotropy and field-induced slow magnetic relaxation with a Raman-like relaxation process.**

Single-Molecule Magnets (SMMs) show promise in a number of technological applications such as molecular spintronics,<sup>1</sup> high-density information storage,<sup>2</sup> and qubits for quantum computation.<sup>3</sup> When the magnetic properties arise from a single paramagnetic ion in an appropriate ligand field, then these molecules are often referred to as Single-Ion Magnets (SIMs). The origin of SMM and SIM behaviour is the presence of an energy barrier ( $\Delta E/k_B$ ) that prevents the reorientation of magnetisation between the  $M_S = \pm S$  components of the ground state  $S$ . Magnetic anisotropy, which depends on the spin-orbit contribution,<sup>4</sup> is difficult to control in polymetallic systems, and hence recent research has been focused on monometallic systems. Monometallic  $\text{Co}^{\text{II}}$  complexes have been found to exhibit both large negative (easy-axis) and large positive (easy-plane) magnetic anisotropy when found in tetracoordinate, pentacoordinate and hexacoordinate geometries.<sup>5</sup> More specifically,  $\text{Co}^{\text{II}}$  ions with an ideal trigonal bipyramidal geometry are expected to exhibit a high easy-plane anisotropy.<sup>6</sup>

We are working towards the synthesis of coordination complexes containing at least one high magnetic anisotropy centre, such as trigonal bipyramidal (TBP)  $\text{Co}^{\text{II}}$ , in order to boost the barrier  $\Delta E/k_B$ . Herein, we report the complex  $[\text{Co}^{\text{II}}\text{Co}_2^{\text{III}}(\mu_3\text{-OH})(\mu\text{-pz})_4(\text{DBM})_3]\cdot 2\text{MeCN}$  (**1**·2MeCN) (Fig. 1),

which is a new solvate of a previously reported  $\{\text{Co}_3\}$  complex, obtained by a different synthetic procedure.<sup>7</sup>

Complex **1** is a mixed-valence isosceles triangle of  $\text{Co}^{\text{II}}/\text{Co}^{\text{III}}$  ions synthesised from the reaction of  $\text{CoCl}_2\cdot 6\text{H}_2\text{O}$  with Hpz (pyrazole) and HDBM (dibenzoylmethane) in MeOH/MeCN in the presence of  $\text{NEt}_3$  (see the ESI†). The crystallographic data can be found in Table S1 (see the ESI†). The  $\text{Co}^{\text{II}}$  centre (Co1) is five-coordinate adopting a slightly distorted TBP geometry, while the two diamagnetic  $\text{Co}^{\text{III}}$  ions (Co2 and Co3) adopt an octahedral geometry. The oxidation states of  $\text{Co}^{\text{II}}$  and  $\text{Co}^{\text{III}}$  were confirmed using Bond Valence Sum (BVS) analysis.<sup>8</sup> Continuous shape measures (CSHMs),<sup>9</sup> which provide an estimate of the distortion from the ideal TBP geometry for Co1, give a value of 0.33 (where 0 corresponds to the ideal polyhedron), confirming a small distortion (Table S2 and Fig. S3 ESI†). The crystal packing is shown in Fig. S4.† Intermolecular interactions are present through hydrogen- $\pi$  and  $\pi$ - $\pi$  interactions between the phenyl and pyrazolate rings of neighbour-

**Fig. 1** The molecular structure of **1**. Colour code:  $\text{Co}^{\text{II}}$ : dark pink (the dark pink polyhedron represents the TBP geometry),  $\text{Co}^{\text{III}}$ : light pink (the light pink polyhedra represent the octahedral geometry), O: red, N: blue, C: grey. Hydrogen atoms are omitted for clarity.

ing molecules, while the shortest intermolecular Co1...Co1' distance is  $\sim 9.3$  Å.

Direct current (dc) magnetic susceptibility measurements were performed on a polycrystalline sample of **1** restrained in eicosane in the 290–2 K temperature range in an applied magnetic field of 1000 Oe (Fig. 2). The  $\chi_M T$  value at room temperature ( $2.45 \text{ cm}^3 \text{ mol}^{-1} \text{ K}$ ) corresponds to a high-spin  $\text{Co}^{\text{II}}$  ion and indicates a spin–orbit coupling contribution (the  $\text{Co}^{\text{III}}$  ions are diamagnetic so for  $g = 2$ ,  $S = 3/2$ ,  $\chi_M T = 1.88 \text{ cm}^3 \text{ mol}^{-1} \text{ K}$ ). Upon cooling,  $\chi_M T$  decreases slowly until  $\sim 50$  K to reach  $2.16 \text{ cm}^3 \text{ mol}^{-1} \text{ K}$  and then decreases rapidly below  $\sim 50$  K to reach  $1.40 \text{ cm}^3 \text{ mol}^{-1} \text{ K}$  at 2 K, indicating zero-field splitting of the ground state. Additionally, magnetisation *versus* field plots at 2, 4 and 6 K did not saturate at the highest available field of 5 T, a further indication of the presence of magnetic anisotropy (Fig. 2 inset).

Microanalysis and powder X-ray diffraction carried out on ground and non-ground samples (Fig. S1 and S2†) show that the lattice solvent is easily lost. Such desolvation could cause changes in the crystal packing, resulting in small changes of the local cobalt environment and hence small changes to the  $\text{Co}^{\text{II}}$   $g$  values and zero-field splitting (ZFS) parameters. High frequency EPR studies on **1** (Fig. S5†) are in agreement and suggest the presence of two discrete species within the microcrystalline powder sample in an  $\sim 50:50$  ratio, having distinct ZFS parameters. Analysis of the EPR data gives the parameters for the two species as:  $g_x = g_y = 2.18$ ,  $g_z = 2.07$  with an  $E/D$  ratio  $\sim 0.13$  and  $g_x = g_y = 2.23$ ,  $g_z = 2.08$  with an  $E/D$  ratio  $\sim 0.17$  (see the ESI†). Using the average of these two sets,  $g_x = g_y = 2.205$ ,  $g_z = 2.075$ , the dc magnetic susceptibility data and the magnetisation curves of **1** were fitted simultaneously using the program PHI<sup>10</sup> (Fig. 2), as described by the following effective Hamiltonian equation (1):

$$\hat{H} = D\hat{S}_z^2 + E(\hat{S}_x^2 - \hat{S}_y^2) + \mu_B \vec{B} \cdot \vec{g} \cdot \hat{S} \quad (1)$$

The first and second terms represent the axial and rhombic ZFS terms, parameterised by  $D$  and  $E$ , respectively,  $\hat{S}$  is the spin operator with components  $\hat{S}_i$  ( $i = x, y, z$ ), and the final

Fig. 2 Variable temperature dc susceptibility data for **1** in a field of 1000 Oe from 290–2 K. Inset: Magnetisation *versus* field plots at temperatures 2, 4, and 6 K for **1**. The red solid lines represent the fit (see the text for details).

term denotes the Zeeman interaction with the local magnetic field,  $\vec{B}$ , parameterised through the Landé  $\vec{g}$  tensor. Fixing the values of  $g_x = g_y = 2.205$  and  $g_z = 2.075$ , and  $\chi_{\text{TIP}} = 0.0009 \text{ cm}^3 \text{ mol}^{-1}$ , where  $\chi_{\text{TIP}}$  stands for the contribution of temperature-independent paramagnetism arising from two  $\text{Co}^{\text{III}}$  and one TBP  $\text{Co}^{\text{II}}$ ,<sup>11</sup> we were able to extract the ZFS parameters  $D = +23.85 (\pm 0.17) \text{ cm}^{-1}$  and  $E = +4.04 (\pm 0.09) \text{ cm}^{-1}$ . The  $E/D$  ratio extracted from the fitting of the magnetic data is  $\sim 0.17$ , consistent with the EPR studies. The magnitude of  $D$  is also consistent with previously reported  $\text{Co}^{\text{II}}$  centres in TBP geometry with easy-plane anisotropy.<sup>12,13</sup>

The relatively high value of the transverse anisotropy indicates significant mixing of the  $M_S = \pm 3/2$  and  $\pm 1/2$  levels, and can be attributed to the small deviation from the ideal TBP geometry and/or the different nature of the ligands in the equatorial positions.<sup>13</sup> Only a few examples of  $\text{Co}^{\text{II}}$  in TBP geometry with easy-plane anisotropy have been found to show slow relaxation of the magnetisation.<sup>13</sup> Therefore, we performed alternating current (ac) magnetic susceptibility measurements. In zero applied dc field, **1** does not display any out-of-phase ac signals, due to efficient zero-field quantum tunnelling. However, by using an applied dc field to suppress tunnelling, compound **1** does display slow magnetic relaxation at low temperature. Variable dc fields (500–5000 Oe) were applied to **1** at 2 K in order to obtain the optimum dc field at which the characteristic relaxation time of the magnetisation ( $\tau$ ) possesses the largest value (Fig. S7, ESI†). The characteristic relaxation times for each field were calculated using CC-FIT,<sup>14</sup> and the  $\tau_{\text{max}}$  value was obtained at 1000 Oe. The frequency dependence of the in-phase and out-of-phase magnetic susceptibility was measured under the optimum dc field for the range of temperatures 1.8–8 K (Fig. 3).

The fitting of the Cole–Cole plot (out-of-phase *versus* in-phase signals) for **1** was performed using CC-FIT<sup>14</sup> (Fig. 4), resulting in small values of the Cole–Cole parameter  $\alpha$  (0.08–0.02) indicative of a relatively narrow distribution of relaxation times. The  $\tau$  values were used to construct an Arrhenius plot for the temperatures 1.8–5 K, from which the relaxation parameters of  $\Delta E/k_B$  (energy barrier) and  $\tau_0$  (pre-exponential factor) at higher temperatures were extracted for **1** (Fig. S8, ESI†). Fitting within the linear region (Orbach relaxation mechanism), the values  $\Delta E/k_B = 23.18 (\pm 2.2) \text{ K}$  and  $\tau_0 = 1.14 \times 10^{-7} \text{ s}$  were extracted. However, the value of  $\Delta E/k_B$  is smaller than the calculated energy difference between the ground and first excited state of  $\sim 50 \text{ cm}^{-1}$  ( $\Delta E_{\text{theor}} = 2\sqrt{D^2 + 3E^2}$ ), a clear indication that other relaxation processes need to be considered. Using eqn (2), we attempted to fit the  $\tau^{-1}$  *versus*  $T$  data but we were not able to extract reasonable values. The terms are the direct, tunnelling, Raman and Orbach contributions, in that order.<sup>15</sup>

$$\tau^{-1} = AH^m T + \frac{B_1}{1 + B_2 H^2} + CT^n + \tau_0^{-1} \exp\left(\frac{-\Delta E}{k_B T}\right) \quad (2)$$

$$\tau^{-1} = B + CT^n \quad (3)$$

In order to avoid over-parameterisation we attempted to fit the  $\tau$  *versus* field ( $H$ ) plot using only the terms for direct and

**Fig. 3** Frequency dependent in-phase (top) and out-of-phase (bottom) susceptibility signals for complex **1** in a 1000 Oe dc applied magnetic field, in the temperature range 1.8–8 K. The solid lines correspond to the fit (CC-FIT).<sup>14</sup>

tunnelling processes (which are dependent on the field) to extract the parameters  $A$ ,  $B_1$ , and  $B_2$ . However, all efforts were unsuccessful, an indication that there is a more complicated dependence of  $\tau$  with the field. Therefore, using only the tunnelling (expressed as the parameter  $B$ ) and Raman contributions (see eqn (3)) we were able to fit the  $\tau^{-1}$  versus  $T$  plot (Fig. 4) affording the values  $B = 926 \text{ s}^{-1}$ ,  $C = 2.3 \text{ K}^{-n} \text{ s}^{-1}$  and  $n = 6.6$ . The exponent factor  $n$  in the Raman process should be equal to 9 for Kramers' ions, or 5 in the presence of low-lying states. However, lower values for  $n$  have been reported in cases where acoustic and optical phonons are involved.<sup>15,16</sup>

In conclusion,  $[\text{Co}^{\text{II}}\text{Co}_2^{\text{III}}(\mu_3\text{-OH})(\mu\text{-pz})_4(\text{DBM})_3]$  is the only reported example of a mixed-valence  $\text{Co}^{\text{II}}/\text{Co}^{\text{III}}$  polynuclear complex containing a single trigonal bipyramidal  $\text{Co}^{\text{II}}$  centre that gives rise to slow magnetic relaxation.<sup>17</sup> In the case of **1**, this arises from a large, easy-plane magnetic anisotropy. To obtain the zero-field splitting parameters, we used high frequency EPR measurements to extract the  $g$  factors. These were then fixed in the simultaneous fitting of the dc magnetic susceptibility and magnetisation data to give the parameters  $D = +23.85 (\pm 0.17) \text{ cm}^{-1}$  and  $E = +4.04 (\pm 0.09) \text{ cm}^{-1}$ . Furthermore, it has been demonstrated recently how the magnetic anisotropy of octahedral  $\text{Co}^{\text{II}}$  is transferred to the overall magnetic anisotropy of a polymetallic  $\{\text{Cr}_7\text{Co}\}$  system. This is of interest for quantum information processing, especially in relation to molecules with a large spin ground state that is characterised by a large, easy-plane anisotropy.<sup>18</sup> Hence, the next step is to develop a route to incorporate high magnetic anisotropy trigonal bipyramidal  $\text{Co}^{\text{II}}$  centres into exchange-coupled polymetallic systems that contain multiple paramagnetic centres.

**Fig. 4** The Cole–Cole plot of the ac magnetic susceptibility of **1** at 1000 Oe (top). The solid lines correspond to the fit (CC-FIT). The plot of  $\tau^{-1}$  versus  $T$  for **1** in the temperature range 1.8–5 K (bottom). The red solid line corresponds to the fit using eqn (3) (see the text for details).
