Anti-inflammatory effects of cinnamon extract and identification of active compounds influencing the TLR2 and TLR4 signaling pathways†

Anne Schink,^{‡a} Katerina Naumoska,^{‡a,b} Zoran Kitanovski,^a Christopher Johannes Kampf,^{‡a,c} Janine Fröhlich-Nowoisky,^{‡a} Eckhard Thines,^{d,e} Ulrich Pöschl,^{‡a} Detlef Schuppan^{§f,g} and Kurt Lucas^{‡g}*

Purpose: Inflammatory processes are involved in many diseases. The bark of *Cinnamomum verum* and its extracts are well known for anti-inflammatory effects, but the underlying active compounds and chemical mechanisms are not yet fully identified. The objective of this study was to elucidate how cinnamon extract, specifically active compounds, and their combinations influence the signaling pathways of inflammation, especially through toll-like receptors TLR2 and TLR4. **Methods:** Bioassay-guided fractionation was performed for standard ethanolic cinnamon extract using high performance liquid chromatography followed by compound identification in the determined active fractions by high-resolution mass spectrometry and gas chromatography-mass spectrometry. THP-1 monocytes were pre-incubated with cinnamon extract, cinnamon fractions or its compounds and stimulated with lipopolysaccharides (LPS), followed by determination of interleukin 8 (IL-8) secretion, and phosphorylation of protein kinase B (Akt), nuclear factor (NF)- κ B inhibitor alpha ($\text{I}\kappa\text{B}\alpha$) and p38. Furthermore, testing was performed in stimulated HEK-TLR2 and HEK-TLR4 reporter cells for direct receptor agonistic effects. **Results:** Among the identified compounds, *trans*-cinnamaldehyde and *p*-cymene significantly reduced the LPS-dependent IL-8 secretion in THP-1 monocytes. Synergistic anti-inflammatory effects were observed for combinations of *trans*-cinnamaldehyde with *p*-cymene, cinnamyl alcohol or cinnamic acid. Moreover, cinnamon extract as well as *trans*-cinnamaldehyde and *p*-cymene mitigated the phosphorylation of Akt and $\text{I}\kappa\text{B}\alpha$. **Conclusions:** *Trans*-cinnamaldehyde and *p*-cymene contribute to the strong anti-inflammatory effects of cinnamon extract. Furthermore, our experiments indicate that also synergistic effects among compounds that do not exhibit anti-inflammatory effects themselves might be present to positively influence the beneficial effects of cinnamon bark extract.

Introduction

Regardless of the origin, inflammatory activities on the molecular level can be described as variations of a cyclic process, involving innate immune activation. Toll-like receptors, like TLR2 and TLR4, can sense both Pathogen-associated and Damage-associated molecular pattern (PAMP, DAMPs) and once activated, they trigger the secretion of pro-inflammatory cytokines such as IL-1 β and tumor necrosis factor (TNF- α), the generation of reactive oxygen and nitrogen species (ROS, RNS) and the release of DAMPs. These molecules cause in turn additional receptor stimulation, which provoke further immune responses.^{1,2} The activation of TLR4 and the translocation of the transcription factor NF- κ B into the cell nucleus play a key role in inflammation and chronic diseases. Molecules within the TLR4 signaling cascade are *e.g.* $\text{I}\kappa\text{B}\alpha$, the serine/threonine kinase Akt and mitogen-activated protein

(MAP) kinase p38, who can activate the transcription factors NF- κ B and/or activator protein 1 (AP-1). Both transcription factors contribute to the expression of several pro-inflammatory cytokines, e.g. IL-1, IL-6, IL-8 and TNF- α .^{3,4} Acute and chronic inflammation are part of many severe inflammatory diseases, including autoimmune diseases, allergies, organ fibrosis and dysfunction.^{5–8} Some synthetic substances, e.g. eritoran and TAK-242 (Resatorvid), inhibit TLR4 signaling *via* the intravenous route and are explored for the treatment of sepsis.^{9–11} Some natural compounds, e.g. epigallocatechin-3-gallate and 6-shogaol are modestly TLR4 inhibitory, but also regulate many other pathways.^{11–13} However, to date, no effective orally active TLR4 antagonists are accessible for clinical usage.

Natural compounds have been used since ancient times in traditional medicines, but their potential to modulate inflammatory pathways has only recently been discovered.¹⁴ The dried bark of *Cinnamomum verum* (Lauraceae), an evergreen tall tree, is one of the oldest known spices. Besides the usage as natural flavoring and fragrance additive in food, beverages and perfumes, cinnamon has also been used in traditional medicine, e.g. for prevention of nausea and vomiting, as treatment of common cold, cardiovascular diseases, chronic gastrointestinal disorders, or as general stimulant. Different cinnamon species are reported to be used in food industry and/or traditional and modern medicine, e.g. *Cinnamomum cassia*, *Cinnamomum verum*, *Cinnamomum burmanii*, *Cinnamomum loureirii*, *Cinnamomum tamala* and *Cinnamomum cordatum*. The preferred cinnamon species in food industry is *Cinnamomum verum*, whereas in the pharmaceutical industry, *Cinnamomum cassia* and *Cinnamomum verum* are used interchangeably.¹⁵ From current literature, cinnamon extract is known to possess anti-inflammatory effects in a mouse model of alcohol-induced fatty liver, on colitis in mice with IL-10 knockout,^{16–18} in models of arthritis and diabetes^{19,20} and in experimental autoimmune encephalitis (EAE), a model of multiple sclerosis.²¹ Ethanolic extracts of *Cinnamomum verum* have shown anti-inflammatory properties by suppression of nitric oxide (NO), TNF- α , IL-1 β and IL-6 production as well as blocking the activation of NF- κ B in different LPS-stimulated cells.^{22,23} *Trans*-cinnamaldehyde has been identified as major active compound in *Cinnamomum verum* bark extract,²⁴ with reported anti-neuroinflammatory,²² antiallergic,²⁵ anticancer, antifungal, antidiabetic and general anti-inflammatory effects.^{25–28} Despite some toxicity at high doses of cinnamaldehyde, this compound is considered safe and well tolerated in humans and animals. An acceptable daily intake of 1.25 mg kg⁻¹ is suggested by the food and drug administration (FDA) and European food safety authority (EFSA).²⁷ Suppression of TLR4 receptor dimerization is described as one mechanism of the anti-inflammatory effects of cinnamaldehyde,²⁹ but cinnamaldehyde also mediates TLR4-independent beneficial effects e.g. in diabetes by upregulation of peroxisome proliferator-activated receptor gamma (PPAR γ) gene expression.³⁰ Coumarin, another phytochemical, is one of the more critical compounds that can be present in cinnamon and is reported to possess

hepatotoxic and carcinogenic properties. A tolerable daily intake (TDI) of 0.1 mg coumarin per kg bodyweight has been established by the EFSA.^{31,32} The content of coumarin within the different cinnamon species strongly varies. Rather low concentrations (from below detection limit up to 297 mg kg⁻¹) can be found in *Cinnamomum verum*, whereas *Cinnamomum cassia* contains markedly more coumarin (from 1740 mg kg⁻¹ up to 7670 mg kg⁻¹).³³ In addition to cinnamaldehyde, further compounds present in cinnamon extract, e.g. *o*-methoxycinnamaldehyde, cinnamyl alcohol, benzyl benzoate, eugenol and cinnamic acid also showed anti-inflammatory properties by inhibiting NO production. Cinnamaldehyde, *o*-methoxycinnamaldehyde and benzyl benzoate also induced a strong inhibition of TNF- α production.²⁴ Further studies confirmed the cinnamaldehyde-dependent inhibition of pro-inflammatory cytokine secretion.^{34,35} Cinnamon extract, a complex natural matrix, may contain additional compounds contributing to the strong anti-inflammatory activity. Moreover, its biological activities may be positively or negatively modulated by such other compounds. Therefore, the objective of this work was to study the anti-inflammatory effects of *Cinnamomum verum* extract and to identify further compounds or combinations of compounds contributing to its potent (TLR-mediated) anti-phlogistic activity.

Materials and methods

Cell cultures and treatments

THP-1 cell line. The THP-1 monocyte-macrophage cell line TIB-202 (ATCC) was cultured in RPMI 1640 medium (Thermo Fisher Scientific, Darmstadt, Germany) supplemented with 10% fetal calf serum (FCS; heat-inactivated) (Biochrom, Berlin, Germany), 1% penicillin/streptomycin (Thermo Fisher Scientific) and 0.05 mM β -mercaptoethanol (Sigma-Aldrich, Darmstadt, Germany) in a humidified atmosphere of 5% CO₂ at 37 °C. 100 μ l with 4 \times 10⁵ cells per ml were seeded in wells of a 96-well microtiter plate (Greiner Bio-One, Solingen, Germany) and allowed to settle for 1 h. Cell culture experiments with cinnamon extract (70% aqueous ethanolic extract of *Cinnamomum verum* bark, Tinctura Cinnamomi (1:5); Maros Arznei, Fürth, Germany) were performed within a concentration range from 0.03% to 3% extract in cell culture medium or with the same amount of vehicle, 70% aqueous ethanol. Stock solutions with concentration of 4 mg ml⁻¹ of *p*-cymene, methyl salicylate, cinnamyl alcohol, *trans*-cinnamic acid, benzoic acid, *trans*-cinnamaldehyde, stearic acid and palmitic acid (all Sigma-Aldrich, analytical grade) were prepared in 70% aqueous ethanol. Final concentrations of 25 μ g ml⁻¹ substance or the same amount of vehicle were used in cell culture medium. In experiments with isolated cinnamon high-performance liquid chromatographic (HPLC) fractions, 2 \times 250 μ l of the fractions were dried by SpeedVac (Martin Christ, Osterode, Germany) in a 96-well microtiter plate. After disinfection of the plate with 70% aqueous ethanol, 4 \times 10⁵ cells per ml were seeded, shaken for 10 min and were allowed to

settle for 1 h. In all experiments, cells were incubated with extract, compounds or fractions for 2 h at 37 °C, followed by a stimulation of TLR4 with LPS (LPS-EB; from *E. coli* O111:B4, Invivogen, Toulouse, France) at a final concentration of 50 ng ml⁻¹ (4 h at 37 °C).

HEK-TLR2 and HEK-TLR4 cell lines. HEK-Blue hTLR2 cell line (HEK-TLR2) and HEK-Blue hTLR4 cell line (HEK-TLR4) (both Invivogen) were cultured in Dulbecco's Modified Eagle Medium (DMEM) high glucose supplemented with 10% FCS (heat-inactivated), 1% penicillin/streptomycin and 1× HEK-Blue Selection (Invivogen) in a humidified atmosphere of 5% CO₂ at 37 °C. To determine viability, HEK-Blue cells were cultured in the medium described above but without HEK-Blue Selection. For TLR2 and TLR4 responsiveness, cells were cultured in HEK-Blue Detection medium (Invivogen). In 96-well microtiter plates, cinnamon extract (concentration range from 0.01% to 3% extract in cell culture medium), 25 µg ml⁻¹ defined compound or the same amount of vehicle 70% aqueous ethanol were added, followed by seeding of 180 µl per well each with 2.8 × 10⁵ cells per ml. Cells were incubated for 2 h at 37 °C, followed by specific stimulation of receptors with 1 ng ml⁻¹ S-[2,3-bis(palmitoyloxy)-(2RS)-propyl]-[R]-cysteinyl-[S]-seryl-[S]-lysyl-[S]-lysyl-[S]-lysyl-[S]-lysine (Pam2CSK4, HEK-TLR2 cell line; Invivogen) or 100 ng ml⁻¹ LPS-EB Ultrapure (HEK-TLR4 cell line; LPS from *E. coli* O111:B4, Invivogen) over night at 37 °C. Cell viability was measured in both cell lines using the Alamar Blue Assay (Thermo Fisher Scientific) and TLR2/TLR4 activation using HEK-Blue Detection Assay (Invivogen).

Determination of cell viability by the Alamar Blue Assay

The Alamar Blue Assay (Thermo Fisher Scientific) was used according to manufacturer's protocol (10% final concentration of Alamar Blue solution in cell culture medium; incubation overnight at 37 °C). Fluorescence intensity was measured with a microplate reader (Synergy Neo, Biotek, Bad Friedrichshall, Germany) at an excitation wavelength of 560 nm and an emission wavelength of 590 nm.

Determination of IL-8 concentration by ELISA

IL-8 concentration in supernatant of pre-treated THP-1 monocytes was determined using ELISA (BD Biosciences). The sandwich ELISA was performed according to the manufacturer's protocol with optimized washing buffer volume. Supernatant (70 µl per well) was diluted with 30 µl assay diluent to ensure IL-8 concentration within detection range. Absorbance was measured using a Synergy Neo plate reader (Biotek) at a wavelength of 450 nm and a reference wavelength of 570 nm. The program SynergyNeo (Biotek) was used to determine a standard curve (4 parameter logarithmic) per plate with the pipetted standard values. IL-8 concentration of the samples was calculated according to standard curve and dilution factor.

Phosphoprotein determination

Phosphorylation level of Akt, p38 and IκBα in pre-treated THP-1 monocytes were determined by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) followed by

Western Blot analysis. For preparation of a cell lysate, THP-1 monocytes were centrifuged for 5 min at 300g, followed by washing with 500 µl PBS. After another centrifugation for 5 min at 300g, the cell pellet was resuspended in 2× Laemmli sample buffer. The samples were boiled for 10 min at 100 °C and centrifuged for 10 min at 13 000g. Protein concentration of the supernatant was measured using the bicinchoninic acid (BCA) assay (Thermo Fisher Scientific) according to the manufacturer's protocol. 15 µg cell lysates were separated by a 10% SDS-polyacrylamide gel and transferred onto 0.2 µm nitrocellulose membranes (Bio-Rad Laboratories, München, Germany). Afterwards, the membranes were blocked with 5% fat-free milk powder (Cell Signaling Technology, Leiden, The Netherlands) in Tris-buffered saline with 0.05% Tween-20 (TBS-T) for 1 h at RT. The membranes were incubated overnight at 4 °C with the specific primary antibodies for vinculin (mouse, 1:2500; Abcam, Cambridge, UK), tubulin (rat, 1:10 000; Abcam), Akt (pan, 11E7, rabbit, 1:500; Cell Signaling Technology), phospho-Akt (Ser473, D9E, rabbit, 1:1000; Cell Signaling Technology), IκBα (mouse, 1:1000; Cell Signaling Technology), phospho-IκBα (Ser36, 1:30 000, rabbit; Abcam), p38 (9F12, mouse, 1:267; Santa Cruz Biotechnology, Heidelberg, Germany) or phospho-p38 (E-1, mouse, 1:1000; Santa Cruz Biotechnology), each diluted in 5% fat-free milk powder solution. After 3 × 5 min washing with TBS-T, membranes were incubated with the horseradish peroxidase-coupled secondary antibodies mouse-IgG, rabbit-IgG or rat-IgG (all goat, 1:10 000; Dianova, Hamburg, Germany) for 2 h at RT, each diluted in TBS-T. Afterwards, membranes were washed 5 × 5 min with TBS-T, followed by development of the protein bands using an enhanced chemiluminescence system ECL-plus (Thermo Fisher Scientific) according to manufacturer's protocol.

Determination of transcription activity in HEK-Blue cells

The inducible reporter gene secreted embryonic alkaline phosphatase (SEAP) of the HEK-TLR2 cell line is under control of the IFNβ minimal promoter fused to five NF-κB and AP 1 binding sides. The SEAP of the HEK-TLR4 cell line is under control of the IL-12 p40 minimal promoter fused to five NF-κB and AP-1 binding sides (InvivoGen). Production of SEAP was determined using the HEK-Blue Detection Assay. Pre-treated cells, which were cultured in HEK-Blue Detection medium, were measured for their TLR2 stimulation (HEK-TLR2 cell line) and TLR4 stimulation (HEK-TLR4 cell line) using a Synergy Neo plate reader at a wavelength of 640 nm.

Fractionation of the cinnamon extract

Cinnamon extract (70% aqueous ethanolic extract of *Cinnamomum verum* bark, Tinctura Cinnamomi (1:5); Maros Arznei, Fürth, Germany) was fractionated by a preparative HPLC-DAD (Agilent 1260 Infinity; Agilent Technologies, Waldbronn, Germany) system equipped with a fraction collector. For this purpose, an HPLC-UV method was developed on a Zorbax Eclipse XDB C18 column (150 × 4.6 mm; 5 µm; Agilent Technologies) connected to a security guard C18 column

(Agilent). Gradient elution with a mobile phase composed of 0.1% formic acid in water (A) (Sigma-Aldrich) and acetonitrile (B) (Fisher Scientific) was applied at 25 °C and a flow rate of 1 ml min⁻¹: 30% B (0–20 min), 30%–100% B (20–25 min), 100% B (25–45 min), 100%–30%B (45–47 min), 30%B (47–60 min). Before injection (400 µl), 70% aqueous ethanolic cinnamon extract was diluted with water (Milli-Q, Millipore, Darmstadt, Germany) at a ratio 1 : 3 v/v and filtered through a Corning® Costar® Spin-X® polypropylene centrifuge tube filters with 0.22 µm cellulose acetate membranes (Sigma-Aldrich). Chromatograms were acquired at several UV wavelengths (210 nm, 250 nm, 280 nm and 300 nm), using UV/Vis DAD.

Identification of compounds in the anti-inflammatory fractions

Cinnamon extract fractions with anti-inflammatory properties, determined by cell culture-based assays, were further analyzed using high-resolution mass spectrometry (HRMS) and gas chromatography–mass spectrometry (GC-MS). For the HRMS analysis (Agilent 1260 Infinity coupled to Agilent Technologies 6540 UHD Accurate-Mass quadrupole-time-of-flight (Q-TOF) LC/MS), fractions (1 ml) were evaporated until dryness, redissolved in absolute ethanol (40 µl; Sigma-Aldrich) and injected into the mass spectrometer (without using a column). The analysis was performed using acetonitrile/0.1% aqueous formic acid (7/3, v/v) as a mobile phase at a flow rate of 0.2 ml min⁻¹. The injection volume was 10 µl. Electrospray ionization (ESI) in positive and negative ion mode was used for ionization of the compounds in the extract fractions. Source conditions were as follows: gas and sheath gas temperatures 325 °C and 295 °C, respectively, drying gas 5 l min⁻¹, sheath gas flow 12 l min⁻¹, nebulizer gas 20 psig, capillary and nozzle voltages 3500 V and 2000 V, respectively. The Q-TOF MS conditions were the following: fragmentor 176 V, skimmer 46 V, Oct 1RF Vpp 750 V. MS and MS² spectra were recorded in the *m/z* range 20–800. Collision energy of 30% was used to fragment the precursor ions observed in the MS spectra.

GC-MS (HP 6890 gas chromatograph coupled to a single quadrupole HP 5972 mass spectrometer, Hewlett-Packard) was used to further separate compounds from the anti-inflammatory HPLC fractions on a DB-5MS + DG column (30 m × 0.250 mm I.D.; 0.25 µm, Agilent (J&W)) using a split injection (1 : 1 ratio) at an injection volume of 1 µl and an injector temperature of 260 °C. The GC oven program was as follows: hold at 50 °C for 1 min, then heating at 4 °C min⁻¹ rate to 300 °C and final hold at 300 °C for 15 min. The temperature of the GC-MS transfer line was set at 290 °C. Helium (>99.9999%, Messer) was used as carrier gas with a constant flow of 1.2 ml min⁻¹. Electron impact ionization (EI) mass spectra were recorded at ionization energy of 70 eV. Recorded chromatograms in the *m/z* range 35–600 were processed using a NIST 2005 mass spectral library. Compounds present in the anti-inflammatory fractions were separated and analyzed both in non-derivatized and derivatized form (silylated with trimethylsilyl methylsulfinate (SILMAS); Sigma-Aldrich). The solvent from the non-deri-

vatized HPLC fractions (1 ml) was evaporated and redissolved in absolute ethanol (40 µl; ≥99.8%, GC). To derivatize the polar compounds in the HPLC fractions, they (1 ml) were first dried under nitrogen, followed by reconstitution of the residue in 200 µl dichloromethane (Roth) and subsequent addition of 200 µl SILMAS reagent. After 10 min, derivatized HPLC fractions were finally dried under nitrogen and redissolved in dichloromethane (500 µl).

Statistical analysis

Analysis of variance (ANOVA) was performed to analyze variance between different experimental groups. Unpaired *t*-test using GraphPad Prism version 5.01 for Windows (GraphPad Software, San Diego, California, USA, <http://www.graphpad.com>) was performed to test the statistical significance of the results. *P* < 0.05 was considered significant. In all graphs, error bars depict standard deviation.

Results

Dose-dependent anti-inflammatory effects of cinnamon extract on TLR pathways

To analyze whether cinnamon extract interferes with TLR signaling pathways in *in vitro*, THP-1 monocytes were incubated with cinnamon extract, followed by LPS-stimulation. Viability of cells treated with varying concentrations was above 92% in all cases compared with untreated cells (Fig. 1a). Since small amounts of ethanol are reported to result in a reduced LPS-dependent TLR4 response,³⁶ which was also observed in our experiments (Fig. 1b), IL-8 secretion of ethanol-treated THP-1 monocytes (Fig. 1c) was set to 100% to display only cinnamon-dependent effects. A dose-dependent decrease of IL-8 secretion was observed in THP-1 monocytes treated with cinnamon extract compared to control. High viability of the cells largely excluded any toxic effects of the cinnamon extract that may have affected IL-8 secretion. Treatment with 0.6%, 1% and 3% cinnamon extract resulted in dose-dependently decreased IL-8 secretion normalized to viability when compared to the ethanol control (Fig. 1d).

Furthermore, the potency of cinnamon extract to specifically inhibit the TLR4 receptor was tested using a comparative assay with Pam2CSK4 (a TLR2 ligand)-stimulated HEK-TLR2 and LPS-EB Ultrapure (a TLR4 ligand)-stimulated HEK-TLR4 cells. Since the nature of their intracellular signaling cascade upon stimulation is partly comparable, differences in their inflammatory response should be related to direct interference with TLR4. Viability of HEK-TLR2 and HEK-TLR4 cells treated with 0.01% to 3% cinnamon extract was above 80% compared to respective ethanol-treated cells (Fig. 2a). A comparable dose-dependent decrease of NF-κB and AP-1 activation normalized to viability was observed in both activated cell lines after incubation with cinnamon extract (Fig. 2b), which was significant for treatment with 0.3% to 3% cinnamon extract compared to the respective ethanol control. No significant differences

Fig. 1 Dose-dependent viability and anti-inflammatory effects of cinnamon extract in THP-1 monocytes. THP-1 monocytes were incubated with cinnamon extract or vehicle (70% ethanol), followed by stimulation of TLR4 activity with LPS-EB. a: Viability was measured using the Alamar Blue Assay and is displayed in % of viability untreated cells. b: IL-8 concentration (pg ml^{-1}) was measured using ELISA. c: IL-8 concentration (1b) in % of corresponding vehicle-treated cells. d: IL-8 secretion (1c) divided by viability (1a). All figures: data represent means \pm SD ($n = 9$); unpaired t -test with $*p < 0.05$, $***p < 0.0005$ compared to respective ethanol control.

Fig. 2 Dose-dependent viability and anti-inflammatory effects of cinnamon extract in HEK-TLR2 and HEK-TLR4 cells. HEK-TLR2 cells (grey, dashed line) and HEK-TLR4 cells (black, full line) were incubated with cinnamon extract or vehicle (70% ethanol), followed by stimulation of TLR2 with Pam2CSK4 (HEK-TLR2 cells) or TLR4 with LPS-EB Ultrapure (HEK-TLR4 cells). a: Viability was measured using the Alamar Blue Assay and is displayed in % of ethanol-treated cells. b: TLR2 or TLR4 receptor response were determined measuring NF- κ B- and AP-1-dependent SEAP production normalized to ethanol control and divided by viability (2a). All figures: data represent means \pm SD ($n = 5$); unpaired t -test: $*p < 0.05$, $***p < 0.001$ compared to respective ethanol control, no significance in comparison between cell lines.

occurred when comparing the inflammatory activity between both cell lines.

Fractionation of cinnamon extract and identification of anti-inflammatory compounds

To identify all major compounds responsible for specific anti-inflammatory effects, cinnamon extract was fractionated using preparative HPLC-DAD (Fig. 3). Fifteen fractions (A–O;

Table S1†) were collected and tested for their anti-inflammatory potential in cell culture-based analysis. Seven fractions induced a significant reduction of IL-8 secretion normalized to viability in LPS-stimulated THP-1 monocytes (Fig. 4). The fractions that showed a TLR4 response below 77% of the respective solvent controls were further analyzed using HRMS and GC-MS.

HRMS spectra of the fractions acquired in both positive (+) and negative (–) ion mode, usually showed complex ion pat-

Fig. 3 Fractionation of cinnamon extract using HPLC-DAD. Chromatogram of cinnamon extract fractionation at wavelength of 280 nm. Marked in grey: cinnamon fractions with anti-inflammatory effects in LPS-stimulated THP-1 monocytes (Fig. 4).

Fig. 4 Cinnamon fractions with anti-inflammatory effects in THP-1 monocytes. THP-1 monocytes were incubated with cinnamon fractions or respective solvent (acetonitrile/0.1% formic acid in water), followed by stimulation of TLR4 with LPS-EB. IL-8 concentration was measured using ELISA, viability was measured using the Alamar Blue Assay and was normalized to viability of untreated cells. Data are displayed as IL-8 concentration divided by normalized viability and normalized to solvent-treated cells. Seven fractions showed TLR4 response below 77%: fraction B: 16.9% of solvent control, fraction D: 50.9%, fraction E: 41.1%, fraction F: 22.8%, fraction G: 40.9%, fraction I: 76.4% and fraction M: 65.4%. Data represent means \pm SD of 3 independent experiments (each with $n = 3$); unpaired t -test (only anti-inflammatory effects marked): *** $p < 0.0001$ compared to solvent control.

terns. Fraction M, the sole colored (yellowish) fraction, showed an (–)ESI-MS spectrum containing mass peaks at m/z 255.23, 283.26, 311.17, 329.23 and 529.46 (Fig. S1a†). The ion with m/z 311.17, as well as its product ion (m/z 183.01) in the MS² appeared also in the blank. Mass peaks at m/z 255.23 and m/z 283.26 could be assigned to palmitic and stearic acid,³⁷ in agreement with Mass Hunter (Agilent) formula calculator hits (C₁₈H₃₆O₂ and C₁₆H₃₂O₂, respectively) and comparison to injected standards. The ion with m/z 329.23 and its product ion with m/z 171.1 indicated the presence of 9,10,13-trihydroxy-11-octadecenoic acid (9,10,13-TriHOME(11)),^{38,39} in line

with Mass Hunter software hits (C₁₈H₃₄O₅). The molecular ion at m/z 529.46 was tentatively identified as octadecyl 3,5-di-*tert*-butyl-4-hydroxyhydrocinnamate (C₃₅H₆₂O₃),⁴⁰ which is known as a food antioxidant (Irganox 1076). Due to the chemical complexity of fractions B, D, E, F, G and I observed in HRMS, further separation of the compounds in a second chromatographic dimension would be needed to identify all active compounds.

As an alternative, a GC-MS method was developed to separate the compounds in the anti-inflammatory HPLC fractions. The method enabled us to identify the following compounds in the non-derivatized fractions: *p*-cymene and methyl salicylate (fraction B), 1-tetradecanol (myristyl alcohol) (fraction D), cinnamyl alcohol (fraction F) and cinnamaldehyde (fraction M), while in the derivatized fractions, trimethyl silyl esters of only three compounds were observed: cinnamyl methyl ether, cinnamic and benzoic acids (fraction F) (Fig. S1b†).

Where possible, the compounds tentatively identified in the cinnamon extract by HRMS and GC-MS (Table S2†) were purchased as pure reference compounds and tested for their anti-inflammatory effects.

Identification of *trans*-cinnamaldehyde and *p*-cymene as anti-inflammatory compounds

Standard solutions of pure compounds which were identified in the anti-inflammatory fractions of cinnamon extract were tested in THP-1 monocytes for their effects on LPS-dependent IL-8 secretion in THP-1 cells (Fig. 5). *trans*-Cinnamaldehyde and *p*-cymene significantly reduced IL-8 secretion normalized to viability in LPS-stimulated THP-1 monocytes. Furthermore, *trans*-cinnamaldehyde and *p*-cymene were additionally tested in the HEK-TLR2/HEK-TLR4 comparative assay system on TLR4 specific antagonism (Fig. 6). A decrease of SEAP production normalized to viability was observed in LPS-stimulated HEK-TLR4 and Pam2CSK4-stimulated HEK-TLR2 cell lines after incubation with *trans*-cinnamaldehyde compared to the vehicle control (Fig. 6a). In both cell lines, comparable anti-inflammatory effects (10 $\mu\text{g ml}^{-1}$ *trans*-cinnamaldehyde) or a significantly lower inflammatory signal in HEK-TLR2 compared to HEK-TLR4 cells (25 $\mu\text{g ml}^{-1}$ and 50 $\mu\text{g ml}^{-1}$ *trans*-cinnamaldehyde) were observed. In contrast, *p*-cymene did not reduce Pam2CSK4- or LPS-induced stimulation in HEK-TLR2 and HEK-TLR4 cells (Fig. 6b).

Possible synergistic anti-inflammatory effects of compounds

Therapeutic herbal extracts are highly complex matrices with beneficial health effects usually not based on a single compound. Often, the overall efficacy in a mixture is not only due to additive, but even to synergistic effects.^{41–43} Since *trans*-cinnamaldehyde showed the highest anti-inflammatory effect in THP-1 monocytes (Fig. 5), several identified compounds were separately pooled with *trans*-cinnamaldehyde to test for possible synergistic effects. Strong anti-inflammatory synergistic effects could be the possible explanation for the combined activity of *trans*-cinnamaldehyde with *p*-cymene, cinnamyl alcohol or cinnamic acid (Fig. 7). These effects were not only

Fig. 5 Anti-inflammatory effects of select cinnamon compounds. THP-1 monocytes were incubated with $25 \mu\text{g ml}^{-1}$ of defined compounds present in cinnamon extract or vehicle (70% aqueous ethanol), followed by stimulation of TLR4 with LPS-EB. IL-8 secretion was measured using ELISA, viability was measured using the Alamar Blue Assay and was normalized to viability of untreated cells. Data are displayed as IL-8 concentration divided by normalized viability and normalized to vehicle-treated cells. Data represent means \pm SD of 3 independent experiments (each with $n = 3$); unpaired t -test: * $p < 0.05$; *** $p < 0.0001$ compared to solvent control.

significant compared to the vehicle control alone, but also when compared to the combination of *trans*-cinnamaldehyde with vehicle. Treatment with *trans*-cinnamaldehyde and ethanol control led to a reduction of IL-8 secretion to a level of 30.7% compared by treatment with ethanol alone. Combined treatment of *trans*-cinnamaldehyde with cinnamic acid further reduced IL-8 secretion to a level of 13.4%, a combination of *trans*-cinnamaldehyde with *p*-cymene to 11.2% and the combination of *trans*-cinnamaldehyde with cinnamyl alcohol to 3.2%.

Effects on phosphorylation of TLR signaling pathway molecules

Possible mechanisms by which cinnamon extract and its active compounds, *trans*-cinnamaldehyde and *p*-cymene mitigate the LPS-induced production of pro-inflammatory cytokines in THP-1 monocytes, were investigated by the phosphorylation ratio of the molecules Akt, I κ B α and p38.

Only slight changes in protein level of Akt were observed in THP-1 monocytes after different treatments (Fig. 8a), whereas Akt phosphorylation (Fig. 8b) was strongly mitigated after treatment with cinnamon extract, *trans*-cinnamaldehyde and *p*-cymene. The same effects were observed for the relative ratio of phospho-Akt to Akt protein level (Fig. 8c). Compared to negative control, I κ B α protein level was reduced in THP-1 monocytes after LPS treatment (Fig. 9a). This reduction was mitigated after treatment with cinnamon extract, *trans*-cin-

Fig. 6 Anti-inflammatory effects of *trans*-cinnamaldehyde and *p*-cymene in HEK-TLR2 and HEK-TLR4 cells. HEK-TLR2 and HEK-TLR4 cells were incubated with *trans*-cinnamaldehyde, *p*-cymene or vehicle (70% aqueous ethanol), followed by stimulation of TLR2 with Pam2CSK4 (HEK-TLR2 cells) or TLR4 with LPS-EB Ultrapure (HEK-TLR4 cells). TLR2 or TLR4 receptor response was determined measuring NF- κ B- and AP-1-dependent SEAP production, viability was measured using the Alamar Blue Assay and was normalized to viability of untreated cells. Data are displayed as receptor activity divided by normalized viability. Data represent means \pm SD ($n = 5$); unpaired t -test: ** $p < 0.01$ comparison of both cell lines; *** $p < 0.0001$ compared to ethanol.

namaldehyde and *p*-cymene, which was significant for treatment with *trans*-cinnamaldehyde. Treatment of LPS-stimulated THP-1 monocytes with cinnamon extract, *trans*-cinnamaldehyde and *p*-cymene resulted in a mitigation of I κ B α phosphorylation, which was significant for the treatment with cinnamon extract and *trans*-cinnamaldehyde compared to solvent control (Fig. 9b). Significant attenuation was observed for all three treatments for the relative ratio of phospho-I κ B α to I κ B α protein (Fig. 9c). After the different treatments, only slight changes in p38 protein were observed (Fig. 10a). Treatment with cinnamon extract and *p*-cymene resulted in a small but significant increase of p38 phosphorylation (Fig. 10b). A sig-

Fig. 7 Synergistic anti-inflammatory effects of cinnamon extract compounds in THP-1 monocytes. THP-1 monocytes were incubated with combination of $25 \mu\text{g ml}^{-1}$ *trans*-cinnamaldehyde (CA) and $25 \mu\text{g ml}^{-1}$ additional defined compounds present in cinnamon extract or vehicle (70% aqueous ethanol), followed by stimulation of TLR4 with LPS-EB. IL-8 secretion was measured using ELISA, viability was measured using the Alamar Blue Assay and was normalized to viability of untreated cells. Data are displayed as IL-8 concentration divided by normalized viability and normalized to vehicle-treated cells. Data represent means \pm SD ($n \geq 6$); unpaired *t*-test: *** $p < 0.0001$ all treatments compared to ethanol control (not marked in graph); * $p < 0.05$, ** $p < 0.005$ compared to incubation with CA + ethanol.

nificant increase was also observed for the relative ratio of p-p38 to p38 protein level after *p*-cymene treatment (Fig. 10c).

Discussion

The anti-inflammatory effects observed for cinnamon extract in THP-1 monocytes are in line with those described before where pre-incubation of murine RAW macrophages with 0.1% to 0.4% cinnamon extract lead to a decreased LPS-induced expression of TNF- α mRNA.¹⁶ A comparable dose of ethanolic cinnamon extract (4.5 ml kg^{-1} body weight per day) also showed inhibitory effects in a mouse model of colitis.¹⁷ Furthermore, cinnamon extract apparently interferes with the downstream signaling pathways common for both TLR2 and TLR4, such as the central NF- κ B/AP-1 signaling, which was shown by comparable suppression on the HEK-TLR2 and HEK-TLR4 assay systems.

To identify all major compounds responsible for specific anti-inflammatory effects, bioassay-guided fractionation of cinnamon extract was performed. In the first dimension HPLC was used, followed by GC in the second dimension. Several compounds were identified in the determined active fractions using the GC-MS method and HRMS. Bioassay-guided fractionation is a well-established approach for untargeted, but focused screening of active compounds in complex matrices.^{44–48} From the identified compounds (Table S2†), *p*-cymene, cinnamyl alcohol, cinnamic acid and cinnamal-

dehyde are present in *Cinnamomum verum* extract, with the latter as major active principle.^{15,24,49,50} To the best of our knowledge, the other compounds shown in Table S2† were not reported to be present in cinnamon extract so far. Compounds in commercial extracts may undergo different chemical reactions (*e.g.* degradation, oxidation, and polymerization) and thus impose some issues during chemical analysis. Sometimes even unreliable data regarding the naturally present compounds can be obtained in the case some chemical reactions have already occurred. If some compounds in the commercially available extracts degrade with time, degradants may start a new degradation cascade. This can happen for example, after degradation of the naturally present antioxidants. Further, polymerization processes (oligomers and polymers) could occur by aging of the formulation. Commercial extracts might be enriched with additional compounds like antioxidants, colorants or preservatives. One should also be aware of the compatibility issues between the naturally occurring compounds in the extracts and the excipients, as degradation products may arise from these reactions as well.⁵¹ These effects might impose additional problems with analysis of the commercial plant extract. However, cinnamon tincture is a simple formulation and no compatibility issues with excipients are expected. Moreover, our cinnamon extract showed to be stable during the time of the study, since HPLC chromatograms were always repeatable with no additional peaks appearing during the storage period of at least one year and within the shelf-life of the extract. Moreover, the use of the commercial extract in our experiments reflects the practical source and common supply.

The observed decrease of LPS-induced IL-8 secretion in THP-1 monocytes by *p*-cymene *in vitro* complements reports on its anti-inflammatory effects *in vivo*, *e.g.* in mouse models of elastase-induced emphysema,⁵² carrageenan-induced peritonitis,⁵³ and LPS-induced acute lung injury.⁵⁴ In addition, we could also confirm cinnamaldehyde-dependent anti-inflammatory effects.^{24,27,55} Besides the various beneficial health effects, cinnamaldehyde was also reported to directly suppress TLR4 activation by inhibition of receptor dimerization.²⁹ Furthermore, the disruption of TLR4-MD-2 heterodimers by formation of covalent adducts has been proposed as main mechanism of action for cinnamaldehyde.¹¹ By testing whole cinnamon extract, the cinnamaldehyde's antagonistic effects for TLR4 were not confirmed in our test system. Therefore, *trans*-cinnamaldehyde was additionally tested in the HEK-TLR2/HEK-TLR4 comparative assay system for TLR4 specific antagonism. The significant decrease of the inflammatory signal in HEK-TLR2 and HEK-TLR4 cells indicates an involvement of *trans*-cinnamaldehyde in both TLR2 and TLR4 signaling pathways, indicating that its mode of action goes beyond a sole TLR4 antagonism and the reported suppression of TLR4 receptor dimerization. Interestingly, a tendency was observed that *trans*-cinnamaldehyde acts as a slightly stronger TLR2- than TLR4-antagonist. Nevertheless, compared to LPS-treated cells, *trans*-cinnamaldehyde resulted in a strong significant reduction of SEAP production in both, TLR2- and TLR4-

Fig. 8 Influence of cinnamon extract, *trans*-cinnamaldehyde or *p*-cymene on Akt phosphorylation. THP-1 monocytes were incubated with cinnamon extract, *trans*-cinnamaldehyde or *p*-cymene, followed by stimulation with LPS-EB. Akt and phospho-Akt protein level were determined using Western Blot analysis. Data are displayed as relative protein expression normalized to vinculin loading control and normalized to the negative control (untreated cells). a: Akt protein level normalized to vinculin, b: phospho-Akt protein level normalized to vinculin, c: phospho-Akt protein level normalized to Akt protein level. Data represent means \pm SD ($n = 3$); unpaired t-test: *** $p < 0.001$, ** $p < 0.005$, * $p < 0.05$ compared to solvent control. *trans*-CA: *trans*-cinnamaldehyde.

transfected, reporter cells. Furthermore, *p*-cymene was tested in the same assay system for TLR4 specific antagonism. We could not demonstrate *p*-cymene mediated attenuation of Pam2CSK4- or LPS-induced SEAP production in HEK-TLR2 and HEK-TLR4 cells. Since both cell lines were co-transfected with human TLR2 or TLR4 receptors and do not exhibit all co-factors of other TLR2/TLR4-related pathways, *p*-cymene may still be active by interfering with pathways not present in these cell lines. We also demonstrated that *trans*-cinnamaldehyde might possess synergistic effects when combined with *p*-cymene, cinnamyl alcohol and cinnamic acid. Nevertheless, the actual ratios of the compounds within the tested cinnamon bark extract might differ from the 1:1 ratio used for the demonstration of possible synergistic effects. *In vivo*, cinnamaldehyde and cinnamyl alcohol can transform into one another depending on redox conditions. In addition, cinnamaldehyde can be oxidized to cinnamic acid.²⁷ One hypothesis

for the synergistic effects of cinnamaldehyde in combination with cinnamic acid and cinnamyl alcohol in our assay system could be that during the assay, a (partial) transformation takes place. A counter-argument for this hypothesis is the pro-inflammatory effect of cinnamyl alcohol observed in our assay when given alone. It is very unlikely that the pH of the system (the pK_a value for *cis*-cinnamic acid is 3.88 and for *trans*-cinnamic acid is 4.44) is responsible for the synergistic effects when combined with cinnamaldehyde, since benzoic acid (with comparable pK_a value of 4.204)⁵⁶ did not show any synergistic effect when combined with *trans*-cinnamaldehyde. Another hypothesis for the synergistic effects of *trans*-cinnamaldehyde with *p*-cymene, cinnamyl alcohol or cinnamic acid could be the possible stabilizing effects of the compounds on the aldehyde functional group of *trans*-cinnamaldehyde. Here, our results provide a first mechanistic basis for the empirical observation that the isolated active compounds of herbal

Fig. 9 Influence of cinnamon extract, *trans*-cinnamaldehyde or *p*-cymene on IκBα phosphorylation. THP-1 monocytes were incubated with cinnamon extract, *trans*-cinnamaldehyde or *p*-cymene, followed by stimulation with LPS EB. IκBα and phospho-IκBα protein level were determined using Western Blot analysis. Data are displayed as relative protein expression normalized to tubulin loading control and normalized to the negative control (untreated cells). a: IκBα protein level normalized to tubulin, b: phospho-IκBα protein level normalized to tubulin, c: phospho-IκBα protein level normalized to IκBα protein level. Data represent means ± SD ($n = 3$); unpaired *t*-test: *** $p < 0.001$, ** $p < 0.001$, * $p < 0.05$ compared to solvent control. *trans*-CA: *trans*-cinnamaldehyde.

medications often do not display the efficacy of complex herbal extracts.^{41–43} Still, the strong combined effects of *trans*-cinnamaldehyde with *p*-cymene, cinnamyl alcohol and cinnamic acid raise the question as to the underlying mechanisms as well as to which extent the *in vitro* effects reported in this study are transferable to *in vivo* systems. Therefore, further studies, especially using specific inhibitors and activators of the TLR4 and other signaling pathways, should help to clarify the exact responsible mechanisms.

Based on the findings of the phosphorylation experiments, it can be concluded that cinnamon extract, *trans*-cinnamaldehyde and *p*-cymene inhibit the pro-inflammatory signal transduction of early TLR2 and TLR4 signaling events. After TLR4 stimulation *via* the phosphatidylinositol 3-kinase (PI3K) pathway, Akt is phosphorylated and regulates the transcriptional activity of NF-κB by the induction of IκBα phosphorylation and degradation.^{3,4} Furthermore, phosphorylation of the

MAP kinase p38, leads primarily to the activation of AP-1, but also of NF-κB, contributing to the expression of several pro-inflammatory cytokines, *e.g.* IL-1, IL-6, IL-8 and TNF-α.^{4,57} Since a rather short incubation time for LPS was chosen (1 h treatment), no significant increase of phospho-Akt activation was observed in the performed experiments. Nevertheless, in line with our findings, cinnamon extract and the cinnamaldehyde derivative 4-hydroxycinnamaldehyde-galactosamine were shown to inhibit the phosphorylation of Akt in different stimulated cell systems.^{58–60} Furthermore, IκBα phosphorylation was significantly reduced in the IL-10^{-/-} colitis mouse model after incubation with cinnamon extract,¹⁷ in a mouse model of myocarditis after incubation with α-bromo-4-chlorocinnamaldehyde⁶¹ and in LPS-induced murine inflammation after incubation with *p*-cymene,⁵⁴ which is in accord with a significant decrease of phospho-IκBα protein level in myeloid cells as found by us. In contrast to our data, mice treated with cinna-

Fig. 10 Influence of cinnamon extract, *trans*-cinnamaldehyde or *p*-cymene on p38 phosphorylation. THP-1 monocytes were incubated with cinnamon extract, *trans*-cinnamaldehyde or *p*-cymene, followed by stimulation with LPS EB. p38 and phospho-p38 protein level were determined using Western Blot analysis. Data are displayed as relative protein expression normalized to vinculin loading control and normalized to the negative control (untreated cells). a: p38 protein level normalized to vinculin, b: phospho-p38 protein level normalized to vinculin, c: phospho-p38 protein level normalized to p38 protein level. maldehyde without further stimulation showed a significant increase of Akt phosphorylation.⁶² This controversy effect might be due to the lack of further stimulation. Contrary to our data, cinnamon extract in IgE-stimulated human intestinal mast cells was reported to attenuate p38 phosphorylation⁶³ and p38 phosphorylation was significantly reduced in THP-1-derived macrophages after treatment with *trans*-cinnamaldehyde,²⁸ whereas cinnamaldehyde was shown to induce phosphorylation of p38 in murine inguinal adipocytes.⁶⁴ In a LPS-induced acute lung injury mouse model, *p*-cymene revealed a dose-dependent significant mitigation of p38 phosphorylation.⁵⁴ Interestingly, the reported decrease of phospho-I κ B α /I κ B α protein ratio after *p*-cymene treatment in the same study has been in line with our data. Whether the disagreement on the influences on p38 phosphorylation might be due to the different interactions of the MAP Kinase in diverse cell types, a lack of transferability between the performed cell culture-

based assays and mouse models, or if rather short incubation times (2 h incubation, followed by 1 h LPS stimulation) that we chose in our experiments or different concentrations might reveal a contrary result would be interesting for further analysis.

Other groups demonstrated beneficial effects for comparable doses of cinnamon extract, *e.g.*, in mouse models of alcohol-induced liver steatosis.¹⁶ Furthermore, 1–6 g cinnamon bark showed beneficial effects in patients with type 2 diabetes, demonstrating a safe usage without major toxic effects.^{65,66} Our data suggest that cinnamon extract might not only play an important role in diabetes, but also in other inflammatory diseases.

A deeper understanding of the underlying mechanisms is necessary to disclose novel strategies for the treatment of inflammation. We show that cinnamon extract, its active compounds *trans*-cinnamaldehyde and *p*-cymene or combinations increase potency of central active compounds opening up novel treatment strategy for diverse inflammatory diseases.
