Diverse chemistry of the dianion $[closo-B_9H_9]^{2-}$: synthesis and reactivity of its mono-anionic derivative [arachno-B₉H₁₂-4,8-Cl₂]⁻†

Florian Schlüter, a Eduard Bernhardt ** and Konstantin Zhizhin*

Attempted protonation of the dianion [closo-B₉H₉]²⁻ under moisture-free conditions did not afford its mono-protonated form $[closo-B_9H_{10}]^-$. The reaction of the former closo-borate with CH₃COOH in dichloromethane yielded a monoanionic product $[B_2O(MeCO_2)_5]^-$. The treatment of $[closo-B_9H_9]^{2-}$ with HCl in dichloromethane afforded its arachno-derivative [arachno-B_oH₁₂-4,8-Cl₂] in a high yield. The experimental solution and quantum-chemically calculated ¹¹B and ¹H NMR spectra of the latter monoanion were found to be in a good agreement; its structure in the solid state was studied by the single crystal X-ray diffraction experiment for the crystal (PPh₄)[arachno-B₉H₁₂-4,8-Cl₂]-0.04HCl. The reaction of [arachno-B₉H₁₂-4,8-Cl₂] with liquid ammonia caused its quantitative conversion into the parent $[closo-B_9H_9]^{2-}$.

Borates $[closo-B_nH_n]^{2-}$ (n > 4) are fundamental building blocks of the boron cluster chemistry (see for example 1-4) and these borates with n = 6-12 were synthesized in 1959–1967. $^{5-9}$ [closo- $B_n H_n$ ²⁻ have three-dimensional aromaticity, while the organic aromatic compounds have two-dimensional aromaticity 10,11 (and literature cited therein). Among the [closo-B_nH_n]²⁻ (n = 6–12), those with n = 7-9 are the least explored.

Borates with an arachno nine-vertex are described in literature since 1960. 12-16 The existence of the monoanion [arachno-B₀H₁₄] has been postulated by Lipscomb, while the first X-ray structural characterization in the form of its cesium(1) salt has been performed by Greenwood et al.;^{4,5} two possible conformations of this monoanion (a and b) are shown in Scheme 1.

Its *i*-configuration appears to be a deviation from Williams theory. The Williams theory postulates that for the generation of the arachno-boranes or carboranes from the nido-clusters, a vertex with the highest connectivity should be removed. 18,19 The examples of the *n*-configuration of the monoanion [arachno-B₉H₁₄]⁻ (in contrast to those of its *i*-configuration) are very rarely reported in literature. They include the dianion $[n-B_9H_{15}]^{2-11}$ as well as the organometallic and coordination compounds, such as $\left[\eta^{6}\text{-}(C_{6}Me_{6})RuB_{8}H_{14}\right]^{20}$ $\left[(dppe)Pt_{2}B_{7}H_{11}\right]^{21}$ and [(PMe₂Ph)₂PtB₇H₁₀NHEt].¹⁴ The structure with *i*-geometry, on

Scheme 1 Known nine-vertex conformations of the monoanion arachno- $B_9H_{14}^-$ (a and b) and that of *nido*- $B_{10}H_{14}$ (c). ¹⁷

the other hand, is obtained by removing a corner with a lower connectivity of nido-B₁₀H₁₄ (Scheme 1c). Such geometry has been however observed for numerous members of the borates, including the dianion $[i-B_9H_{15}]^{2-11}$ and a series of neutral coordination compounds [arachno-B₉H₁₃L].¹⁵ The borate nido-B₁₀H₁₄ has been also assigned to this geometry (see ref. 17 and references therein). The n-configuration has been observed 17 only for one of its halogen-containing derivative, viz., [arachno- B_9H_{12} -4,8- Br_2 , which is a by-product of the synthesis of anti-B₁₈H₂₂ by the reaction of [nido-B₉H₁₂] with HgBr₂ in dichloromethane. 17,22 In the present communication, we describe the products of the reactions of [closo-B₉H₉]²⁻ with various acids and the reactivity of these products.

In the first stage of our investigation, we attempted to protonate $[closo-B_9H_9]^{2-}$ with acetic acid under anhydrous conditions. Dry acetic acid was added to the red-orange solution of (PPh₄)₂[closo-B₉H₉] in dichloromethane and then, the reaction mixture was left under pentane atmosphere for 3 days. This reaction resulted in

Paper NJC

the complete destruction of a polyhedral boron cluster, thus affording the monoanion $[B_2O(MeCO_2)_5]^-$ as a major product, which crystallizes as $(PPh_4)[B_2O(MeCO_2)_5]$ in colorless crystals. ^3 The heteroleptic products $[B_2O(MeCO_2)_5]^-$ and $B_2O(MeCO_2)_4$ were already detected spectroscopically few years ago. ^2^4^2^7 It should be noted that the homoleptic compounds $[B(MeCO_2)_4]^-$ and $B(MeCO_2)_3$ were not described in literature till date.

We also studied the reaction of $(PPh_4)_2[closo-B_9H_9]$ with HCl in dichloromethane. Indeed, the bromine-containing compound $[arachno-B_9H_{12}^-4,8-Br_2]^-$ has been prepared⁶ using the reaction of the $[nido-B_9H_{12}]^-$ with HgBr₂. The treatment of $(PPh_4)_2[closo-B_9H_9]$ with purified gaseous HCl (the oxygen impurities were removed using three condensation–argon saturation cycles) in dichloromethane at -78 °C (the latter makes it possible to remove the remaining moisture impurities) under inert atmosphere afforded

Fig. 1 Labeling scheme of the atoms in the anion [arachno- B_9H_{12} -4,8- Cl_2] and its quantum-chemically calculated structure.

the chlorine-containing monoanion $[arachno-B_9H_{12}-4,8-Cl_2]^-$ as per the following eqn (1):

$$(PPh_4)_2[closo-B_9H_9] + 3HCl \rightarrow (PPh_4)[arachno-B_9H_{12}-4,8-Cl_2] + (PPh_4)Cl$$
 (1)

The calculated structure of this monoanion with a labeling scheme of its atoms is shown in Fig. 1.

The initial red-orange solution of $(PPh_4)_2[closo-B_9H_9]$ in dichloromethane underwent an immediate decolouration after the addition of HCl. The resultant reaction mixture was carefully mixed with a five-fold volume of pentane and colorless crystals were formed after 3 days with high yield (83%).

The reaction of a suspension of (PPh₄)[arachno-B₉H₁₂-4,8-Cl₂] with liquid ammonia at r.t.¹⁹ resulted in the re-closing of this arachno-compound into the initial [closo-B₉H₉]²⁻: after 10 min, the initially colorless reaction mixture turned yellow, following which NH₃ escaped from the mixture and the intensity of its color increased, thus indicating the formation of the closo-borate dianion according to eqn (2):

$$2(PPh_4)[arachno-B_9H_{12}-4,8-Cl_2] + 6NH_3 \rightarrow (PPh_4)_2[closo-B_9H_9] + (NH_4)_2[closo-B_9H_9] + 4NH_4Cl$$
 (2)

The yield of the orange solid product, based on its NMR spectra, was quantitative.

The initial *closo*-borate compound and the products of its transformations were characterized using multinuclear NMR spectroscopy and by the single crystal X-ray diffraction study as; their ¹¹B NMR spectra are shown in Fig. 2 and 3.

In the spectrum b of new compound $(PPh_4)[arachno-B_9H_{12}-4,8-Cl_2]$, the signals of its ¹¹B nuclei split in the integral ratio 2:1:2:2:1:1; the two chlorine-substituted boron atoms have a singlet character. An assignment of the above signals was made

Fig. 2 11 B NMR spectra of the CD₃CN solutions of the initial [$closo-B_9H_9$]²⁻ (a), the chlorine-containing derivative [$arachno-B_9H_{12}-4,8-Cl_2$]⁻ (b) and the product of its reaction with liquid ammonia (c).

The averaged calculated $\delta_{^{11}\mathrm{B}}$. The averaged calculated $\delta_{^{1}\mathrm{H}}$ for the atoms H2. H4 and H8.

using the theoretically calculated ¹¹B NMR values, which are also collected in Table 1.

The bridging hydrogen atoms of [arachno-B₉H₁₂-4,8-Cl₂] were not detected at room temperature using ¹H NMR method due to substantial broadening (due to the dynamic behavior)of the peaks. The same effect is also observed⁶ in its brominecontaining analog [arachno-B₉H₁₂-4,8-Br₂]⁻. The calculated values of $\delta_{^{11}\text{B}}$ for the boron-based framework of [arachno-B₉H₁₂-4,8-Cl₂] were found to be in a good agreement with those experimentally observed (except that for the atom B₆).

The colorless single crystals of the salt (PPh₄)[arachno-B₉H₁₂-4,8-Cl₂] were also characterized using the single crystal X-ray diffraction method;²¹ the molecular structure of its arachnoanion is shown in Fig. 3.

This structure is very similar to that of the parent anion $[arachno-B_9H_{14}]^-$, having the same arrangement of both the backbone and the bridging protons. Two of the residual electron peaks observed in this spectrum were assigned to the HCl molecule with about 4% occupancy. In addition, peaks attributed

Fig. 4 Quantum-chemically calculated structure of the monoanion [arachno- B_9H_{12} -4,8- Cl_2] having C_s symmetric arrangement.

to 3 μ-H and 2 *endo*-H could be found. The bridging proton H10 was evidenced to be deviated from the centrum of the corresponding boron-boron bond, while the same was not observed for the two other bridging protons. The bond distance B9-H10 (1.126 (12) Å) is smaller than that of B4-H10 (1.508 (13) Å). The quantum-chemical B3LYP/6-311G calculations²⁰ showed that such arrangement of the bridging hydrogen atoms in the crystal (PPh₄)- $[arachno-B_0H_{12}-4,8-Cl_2]$ is energetically preferable by 5.83 kJ mol⁻¹ as compared with its C_s -symmetric arrangement (Fig. 4).

Such calculated C_s -symmetric structure contains two μ -H and three endo-H atoms and it was not experimentally detected using the NMR method.

Thus, the dianion [closo-B₉H₉]²⁻ was found to react with gaseous HCl in dichloromethane under anhydrous conditions, affording its halogen-containing derivative [arachno-B9H12-4,8-Cl₂], which undergoes re-closing with NH₃ to form an initial closo-borate dianion.
