# Tunable emission from green to red in the $\text{GdSr}_2\text{AlO}_5:\text{Tb}^{3+}, \text{Eu}^{3+}$ phosphor *via* efficient energy transfer

Yu Zhang, Xuejie Zhang, Haoran Zhang, Lingling Zheng, Yuan Zeng, Yu Lin, Yingliang Liu \* and Bingfu Lei \*

Herein, a series of  $\text{GdSr}_2\text{AlO}_5:\text{Tb}^{3+}, \text{Eu}^{3+}$  phosphors were successfully synthesized through a high temperature solid-state reaction, and their crystal structures as well as photoluminescence properties were investigated in detail. Compared to the intense emission of  $^5\text{D}_0 \rightarrow ^7\text{F}_1$  or  $^5\text{D}_0 \rightarrow ^7\text{F}_2$  transition of  $\text{Eu}^{3+}$ , another strong emission corresponding to  $^5\text{D}_0 \rightarrow ^7\text{F}_4$  was observed. Concentration quenching is not obvious in  $\text{Tb}^{3+}$  or  $\text{Eu}^{3+}$ -doped  $\text{GdSr}_2\text{AlO}_5$  because structure isolation and energy transfer (ET) of  $\text{Gd}^{3+} \rightarrow \text{Eu}^{3+}$  and  $\text{Gd}^{3+} \rightarrow \text{Tb}^{3+}$  were found. Moreover, the energy transfer process from  $\text{Tb}^{3+}$  to  $\text{Eu}^{3+}$  was verified by the overlap of luminescence spectra and the variation of lifetime. Energy transfer mechanism was determined to be a dipole–dipole interaction, and ET efficiency as well as quantum efficiency were also obtained. Moreover, the emission color of  $\text{GdSr}_2\text{AlO}_5:\text{Tb}^{3+}, \text{Eu}^{3+}$  can be tuned from green to red by altering the ratio of  $\text{Tb}^{3+}/\text{Eu}^{3+}$ . These results indicate that the  $\text{GdSr}_2\text{AlO}_5:\text{Tb}^{3+}, \text{Eu}^{3+}$  phosphor is a promising single-component white light-emitting phosphor.

## 1. Introduction

White light-emitting diodes (w-LEDs) with superior advantages, such as high energy efficiency, good physical and chemical stability, long lifetime, and environment friendliness, have been drawing attention and are regarded as the next generation of illumination sources.<sup>1–4</sup> The most available material for light devices involves  $\text{Ce}^{3+}$ -doped yttrium aluminum garnet ( $\text{YAG}:\text{Ce}^{3+}$ ) with blue-LED chips, which has been commercialized.<sup>5,6</sup> Because of the scarcity of red component, it encounters a low color rendering index ( $R_a < 80$ ) and a high color temperature (CCT > 7000 K).<sup>7,8</sup> To overcome these drawbacks, the combination of a UV LED chip with red ( $\text{Ca}_4(\text{PO}_4)_2\text{O}:\text{Eu}^{2+}$ ),<sup>9</sup> green ( $\text{Na}_2\text{Y}_2\text{B}_2\text{O}_7:\text{Ce}^{3+}, \text{Tb}^{3+}$ ),<sup>10</sup> and blue ( $\text{Na}_x\text{Ca}_{1-x}\text{Al}_{2-x}\text{Si}_{2+x}\text{O}_8:\text{Eu}^{2+}$ )<sup>11</sup> to achieve white-light with high  $R_a$  and appropriate CCT is another approach. However, the mixture of different phosphors brings about an inevitable problem of fluorescence re-absorption, resulting in the loss of luminous efficiency.<sup>12,13</sup> Therefore, it is obligatory to develop a single-phase white light-emitting phosphor.

Rare earth ion-doped aluminate phosphors, such as  $\text{LaSr}_2\text{AlO}_5:\text{Ce}^{3+}/\text{Eu}^{2+}$ ,<sup>14,15</sup>  $(\text{La}, \text{Gd})\text{Sr}_2\text{AlO}_5:\text{Ce}$ ,<sup>16</sup> and  $(\text{La}, \text{Gd})\text{Sr}_2(\text{Al}, \text{B})\text{O}_5:\text{Ce}$ ,<sup>17</sup> have been studied extensively due to their cheap raw materials and good chemical and physical stability. The structural properties of this aluminate-based phosphor and the

effect on the luminescence properties have been investigated. However, the luminescence of  $\text{Ce}^{3+}$  and  $\text{Eu}^{2+}$  belong to the f–d transition.<sup>18</sup> Upon reviewing the literature, it is observed that it is difficult to find other rare-earth ions with f–f transition for doping into the  $\text{GdSr}_2\text{AlO}_5$  phosphor. As is well known, co-doping of different rare ions as a sensitizer and activator plays a significant role in obtaining emission *via* energy transfer processes.<sup>19</sup>

$\text{Tb}^{3+}$  and  $\text{Eu}^{3+}$  with characteristic green<sup>20,21</sup> and red<sup>22,23</sup> emissions are widely used in luminescent materials, respectively. Compared to most  $\text{Eu}^{3+}$ -doped phosphors with the dominant emission corresponding to  $^5\text{D}_0 \rightarrow ^7\text{F}_1$  or  $^5\text{D}_0 \rightarrow ^7\text{F}_2$ , the  $\text{Eu}^{3+}$ -doped  $\text{GdSr}_2\text{AlO}_5$  phosphor shows an intensive emission related to  $^5\text{D}_0 \rightarrow ^7\text{F}_4$ . It is clear that  $\text{Tb}^{3+}$  functions as a good sensitizer to improve the luminescence efficiency of  $\text{Eu}^{3+}$  ions in  $\text{Sr}_2\text{MgSi}_2\text{O}_7$ ,<sup>24</sup>  $\text{Na}_3\text{La}(\text{PO}_4)_2$ ,<sup>25</sup>  $\text{CaYAlO}_4$ ,<sup>26</sup> and  $\text{Y}_2\text{O}_3$  (ref. 27) phosphors. In this study, a single-phased  $\text{GdSr}_2\text{AlO}_5:\text{Tb}^{3+}, \text{Eu}^{3+}$  phosphor was synthesized by a conventional solid-state method. The efficient energy transfer from  $\text{Tb}^{3+}$  to  $\text{Eu}^{3+}$  was systematically investigated with steady state fluorescence, lifetime measurement, and the energy transfer efficiency. Moreover, the color of the total emission can be tuned by altering the ratio of  $\text{Tb}^{3+}/\text{Eu}^{3+}$  in the  $\text{GdSr}_2\text{AlO}_5$  host.

## 2. Experimental method

A series of phosphors with the composition of  $\text{GdSr}_2\text{AlO}_5:\text{Tb}^{3+}$ ,  $\text{GdSr}_2\text{AlO}_5:\text{Eu}^{3+}$ , and  $\text{GdSr}_2\text{AlO}_5:\text{Tb}^{3+}, \text{Eu}^{3+}$  were prepared by a conventional high temperature solid-state method under

Guangdong Provincial Engineering Technology Research Center for Optical Agricultural, College of Materials and Energy, South China Agriculture University, Guangzhou 510642, P. R. China. E-mail: [tlei@scau.edu.cn](mailto:tlei@scau.edu.cn)

a reductive atmosphere (5% H<sub>2</sub> + 95% N<sub>2</sub>) at 1500 °C. SrCO<sub>3</sub> (A. R.), Al<sub>2</sub>O<sub>3</sub> (A. R.), Gd<sub>2</sub>O<sub>3</sub> (A. R.), Tb<sub>4</sub>O<sub>7</sub> (99.99%), and Eu<sub>2</sub>O<sub>3</sub> (99.99%) were used as raw materials. They were stoichiometrically weighed and mixed by grinding in an agate mortar for 30 min. After this, they were transferred into ceramic crucibles and calcined in a high-temperature tubular furnace at 1500 °C for 4 h at a heating rate of 3 °C min<sup>-1</sup>. Finally, the samples were cooled down to room temperature in the furnace and ground into powders for subsequent use.

Bruker D8 (voltage 40 kV and current 40 mA) over the 2θ range from 10° to 70° with CuKα radiation (λ = 1.54178 Å) was used to obtain the XRD patterns of GdSr<sub>2</sub>AlO<sub>5</sub>:Tb<sup>3+</sup>,Eu<sup>3+</sup> samples. Hitachi F-7000 spectrophotometers with a 150 W xenon lamp light source were used to obtain the excitation and emission spectra. The morphology of the prepared phosphor was examined by a field-emission scanning electron microscope (Hitachi S-4800). The decay curves were obtained using the Hamamatsu Quantaurus-Tau C11367 fluorescence spectrophotometer. The chromaticity data were calculated by the CIE1931 software. Photoluminescence absolute quantum efficiency (QE) was determined *via* Hamamatsu Quantaurus-QY C11347 using an integrated sphere. All the measurements were conducted at room temperature.

### 3. Results and discussion

#### 3.1 XRD analysis

Fig. 1(a) shows the XRD patterns of the as-prepared GdSr<sub>2</sub>AlO<sub>5</sub> host and Tb<sup>3+</sup>, Eu<sup>3+</sup>-doped phosphor as well as the standard patterns of EuSr<sub>2</sub>AlO<sub>5</sub> (JCPDS 70-2197). The patterns agreed with the crystallographic structure of the JCPDS card 70-2197, and impurity peaks were not found. This result illustrates that the obtained samples are in single phase, and doping of Tb<sup>3+</sup> and/or Eu<sup>3+</sup> ions at low concentrations does not change the crystal structure. In addition, it can be observed from Fig. 1(b) that the diffraction peak positions of the samples are shifted slightly to a higher angle as compared to those of the standard patterns of EuSr<sub>2</sub>AlO<sub>5</sub> (JCPDS 70-2197); this can be due to the replacement of large-size Eu<sup>3+</sup> sites by the smaller-size trivalent ions. Hence, RE<sup>3+</sup> ions were effectively doped into the lattice; this could be confirmed by the slight change in the diffraction peaks.

Fig. 1(c) displays a partial structure of GdSr<sub>2</sub>AlO<sub>5</sub>. As reported previously, the crystal structure of GdSr<sub>2</sub>AlO<sub>5</sub> is isostructural with the standard file of EuSr<sub>2</sub>AlO<sub>5</sub> (JCPDS no. 70-2197, tetragonal, space group *I4/mcm*).<sup>28</sup> Gd atoms will occupy the half 8h sites, and the other half is occupied by the Sr atoms. The cell also contains 4a sites, which are fully occupied by the Sr atoms, and the Al atoms will occupy the 4b sites. The 4c sites and 16l sites are occupied by O, denoted as O<sub>1</sub> and O<sub>2</sub>, respectively. The GdO<sub>8</sub> polyhedron consists of two O<sub>1</sub> atoms and six O<sub>2</sub> atoms, where the latter are shared by four AlO<sub>4</sub> tetrahedral on the adjacent layers, forming an isolated structure. Fortunately, isolation in space weakens the interaction between the paired ions. To some extent, the concentrating quenching effect would be avoided.<sup>29</sup>

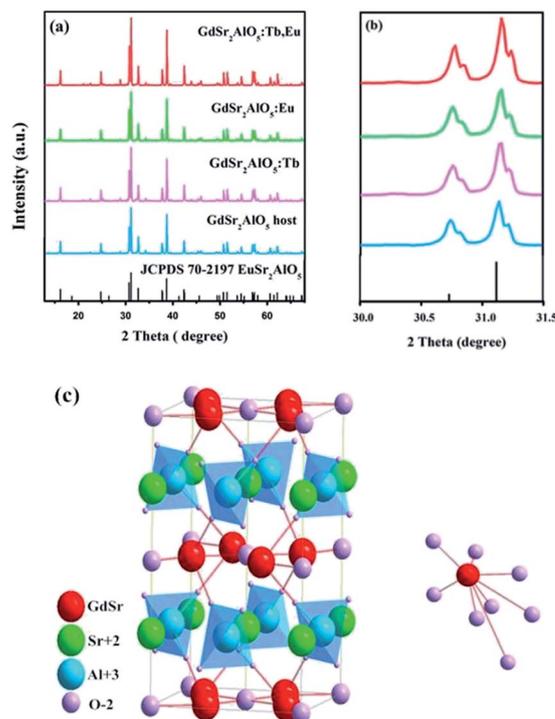

Fig. 1 (a) Representative XRD patterns of the samples. (b) Magnified XRD patterns between 30° and 31.5°. (c) Crystal structure of the GdSr<sub>2</sub>AlO<sub>5</sub> and the coordination environment of GdO<sub>8</sub>.

#### 3.2 SEM with energy dispersive X-ray analysis

Fig. 2(a) displays the morphology of the GdSr<sub>2</sub>AlO<sub>5</sub>:Tb<sup>3+</sup>,Eu<sup>3+</sup> sample. The surface image shows irregular particles with a size range of 5–10 μm. Moreover, as shown in Fig. 2(b), EDS is used to analyze the chemical composition of the GdSr<sub>2</sub>AlO<sub>5</sub>:Tb<sup>3+</sup>,Eu<sup>3+</sup> phosphor, and the result confirms the presence of Gd, Sr, Al, O, Tb, and Eu elements in the phosphor. Compared with the abovementioned XRD results, the EDS results demonstrate that Tb/Eu ions have been successfully incorporated into the GdSr<sub>2</sub>AlO<sub>5</sub> lattice.

#### 3.3 Luminescence properties

The excitation spectrum of GdSr<sub>2</sub>AlO<sub>5</sub>:2%Tb<sup>3+</sup> is shown in Fig. 3(a). The excitation spectrum monitored at 548 nm exhibits a broad band and several weak peaks. The broad band from

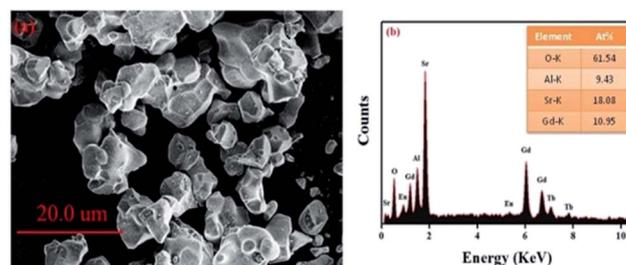

Fig. 2 SEM image (a) and EDS spectrum (b) of GdSr<sub>2</sub>AlO<sub>5</sub>:2%Tb<sup>3+</sup>, 2% Eu<sup>3+</sup>.

200 nm to 250 nm centered at 220 nm is ascribed to the f-d transitions of the  $\text{Tb}^{3+}$  ions, whereas the excitation peaks at 275 and 310 nm originate from the transitions of  $^8\text{S}_{7/2} \rightarrow ^6\text{I}_{7/2}$  and  $^8\text{S}_{7/2} \rightarrow ^6\text{P}_{7/2}$  of the  $\text{Gd}^{3+}$  ions, respectively.<sup>30,31</sup> The appearance of strong excitation sharp bands of  $\text{Gd}^{3+}$  ions confirms that there is an efficient energy transfer from  $\text{Gd}^{3+}$  to  $\text{Tb}^{3+}$ . The emission spectra of the phosphor under 220, 275, and 310 nm excitation in the wavelength range from 400–650 nm are also depicted in Fig. 3(a). There are two groups of lines in the emission spectrum: one group in the region from 400 to 480 nm is derived from the  $^5\text{D}_3 \rightarrow ^7\text{F}_j$  ( $J = 5, 4, \text{ and } 3$ ) transitions of  $\text{Tb}^{3+}$ . The second groups of lines in the wavelength range from 480 to 650 nm originate from the  $^5\text{D}_4 \rightarrow ^7\text{F}_j$  ( $J = 6, 5, 4, \text{ and } 3$ ) transitions. Among these emissions, the  $^5\text{D}_4 \rightarrow ^7\text{F}_5$  transition with a maximum at about 548 nm exhibits the strongest emission intensity. The emission intensity increases with the increasing concentration of  $\text{Tb}^{3+}$ , as presented in Fig. 3(b). Concentration quenching does not occur in  $\text{GdSr}_2\text{AlO}_5:\text{Tb}^{3+}$ .

Fig. 3(c) and (d) present the excitation and emission spectra as well as concentration-dependent luminescence intensity of  $\text{GdSr}_2\text{AlO}_5:\text{yEu}^{3+}$ . The excitation spectrum of the  $\text{Eu}^{3+}$ -activated sample monitoring the emission wavelength at 705 nm contains a broad band in the wavelength range from 220 to 350 nm, corresponding to the charge transfer transition of  $\text{Eu}^{3+}$  ( $\text{O}^{2-} \rightarrow \text{Eu}^{3+}$ ) and several characteristic narrow peaks at 383 nm and 393 nm. They are attributed to  $^7\text{F}_0 \rightarrow ^5\text{G}_2$  and  $^7\text{F}_0 \rightarrow ^5\text{L}_6$  electronic transitions of the  $\text{Eu}^{3+}$  ions. In this band, there should be absorption of transitions from  $^8\text{S}_{7/2}$  to  $^6\text{I}_{7/2}$  level of  $\text{Gd}^{3+}$ , which is too weak and is overlapped with the strong CTB of the  $\text{O}^{2-} \rightarrow \text{Eu}^{3+}$ .<sup>32,33</sup> The emission spectrum consists of multiple band emissions at 587, 607, 622, 657, and 705 nm, which are assigned to the  $^5\text{D}_0 \rightarrow ^7\text{F}_j$  ( $J = 0, 1, 2, 3, \text{ and } 4$ ) transitions of  $\text{Eu}^{3+}$  ions,<sup>34</sup> respectively. Among these emission peaks, the two most intense lines are the emissions located at

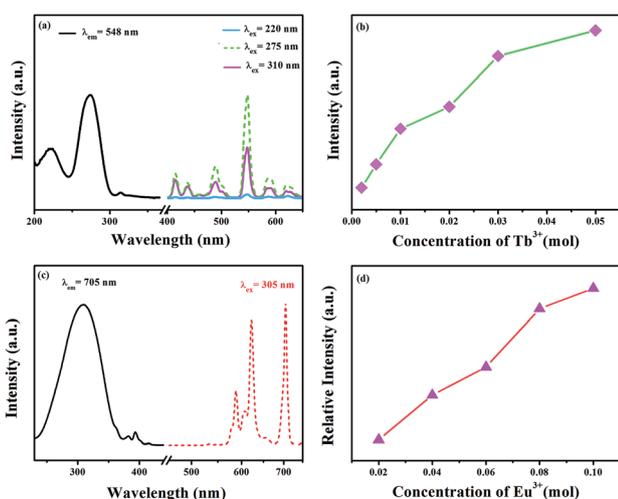

Fig. 3 (a) Excitation and emission spectra of the  $\text{GdSr}_2\text{AlO}_5:2\%\text{Tb}^{3+}$  phosphor. (b) Concentration-dependent luminescence intensity of  $\text{GdSr}_2\text{AlO}_5:\text{xTb}^{3+}$ . (c) Excitation and emission spectra of the  $\text{GdSr}_2\text{AlO}_5:2\%\text{Eu}^{3+}$  phosphor and (d) concentration-dependent luminescence intensity of  $\text{GdSr}_2\text{AlO}_5:\text{yEu}^{3+}$ .

622 and 705 nm. Obviously, the magnetic dipole transition of  $^5\text{D}_0 \rightarrow ^7\text{F}_1$  is stronger than the  $^5\text{D}_0 \rightarrow ^7\text{F}_2$  electronic transition; this indicates that  $\text{Eu}^{3+}$  ions in the  $\text{GdSr}_2\text{AlO}_5$  host occupy a site with a non-inversion symmetry; this is consistent with its structure. Compared to other  $\text{Eu}^{3+}$  phosphors,  $\text{GdSr}_2\text{AlO}_5:\text{Eu}^{3+}$  provides more red components to improve  $R_a$ . Similarly, there is no evident concentration quenching with the change in the  $\text{Eu}^{3+}$  concentration.

The foundation of energy transfer is the spectral overlapping  $\text{Tb}^{3+}$  emission and the  $\text{Eu}^{3+}$  excitation. As is clearly shown in Fig. 4, there are some overlaps between the emission of  $^5\text{D}_3 \rightarrow ^7\text{F}_6$  ( $\text{Tb}^{3+}$ ) and the excitation of  $^7\text{F}_0 \rightarrow ^5\text{G}_{2,3,4,5}$ ,  $^5\text{L}_8$  ( $\text{Eu}^{3+}$ ). Moreover, the excitation of  $^7\text{F}_0 \rightarrow ^5\text{D}_3$ ,  $^5\text{L}_6$  ( $\text{Eu}^{3+}$ ) overlaps with the emission of  $^5\text{D}_3 \rightarrow ^7\text{F}_5$  ( $\text{Tb}^{3+}$ ).<sup>35</sup>

To further investigate the energy transfer process, a series of samples of  $\text{GdSr}_2\text{AlO}_5:2\%\text{Tb}^{3+}, \text{x}\%\text{Eu}^{3+}$  ( $x = 0, 0.5, 1, 2, 3, \text{ and } 5$ ) were prepared whose emission spectra under the excitation at 275 nm are presented in Fig. 5(a). The characteristic sharp emission peaks of  $\text{Tb}^{3+}$  and  $\text{Eu}^{3+}$  are observed. The tendency in the variation of  $\text{Tb}^{3+}$  and  $\text{Eu}^{3+}$  differs significantly. The emission intensity of  $\text{Tb}^{3+}$  at 548 nm decreases remarkably with an increase in the concentration of  $\text{Eu}^{3+}$ , whereas the emission intensity of  $\text{Eu}^{3+}$  increases monotonously. Fig. 5(b) depicts the contribution of different ions in the corresponding emission spectra. The G/R (green to red) ratio continuously decreases notably. Based on the prerequisite of the concentration of  $\text{Tb}^{3+}$  being a constant value, explanation for this phenomenon should be the evidence of energy transfer from  $\text{Tb}^{3+}$  to  $\text{Eu}^{3+}$ .

In spite of steady-state spectra, kinetic spectra are necessary to better analyze the energy transfer mechanism of  $\text{Tb}^{3+} \rightarrow \text{Eu}^{3+}$  in  $\text{GdSr}_2\text{AlO}_5$ . Fig. 6(a) shows the fluorescence decay curves of  $\text{Tb}^{3+}$  emissions, which are obtained under 275 nm excitation and detected at 548 nm. The luminescence curves can be fitted well with the double-exponential expression:<sup>36,37</sup>

$$I(t) = I_0 + A_1 \exp(-t/\tau_1) + A_2 \exp(-t/\tau_2) \quad (1)$$

where  $I$  and  $I_0$  represent the luminescence intensity at time  $t$  and 0,  $A_1$  and  $A_2$  are equal to constants,  $t$  is the time, and  $\tau_1$  and  $\tau_2$  are the rapid and slow lifetimes for exponential components, respectively. As a function of these parameters, the average luminescence lifetime ( $\tau$ ) was determined by the following equation:

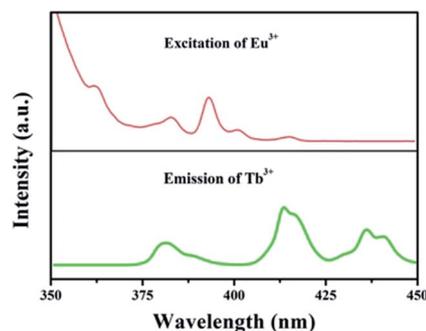

Fig. 4 Spectral overlapping of the PL spectrum of  $\text{GdSr}_2\text{AlO}_5:\text{Tb}^{3+}$  and the PLE spectrum of  $\text{GdSr}_2\text{AlO}_5:\text{Eu}^{3+}$ .

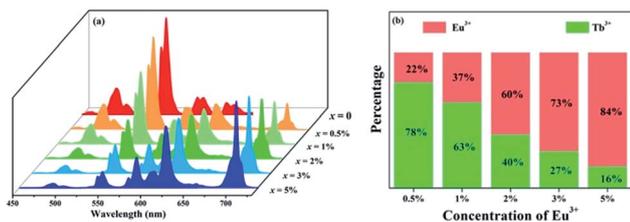

Fig. 5 (a) Emission spectra of  $\text{GdSr}_2\text{AlO}_5:2\%\text{Tb}^{3+}, x\%\text{Eu}^{3+}$  ( $x = 0, 0.5, 1, 2, 3,$  and  $5$ ) under  $275\text{ nm}$  excitation. (b) Variation tendency of the green emission of  $\text{Tb}^{3+}$  and the red emission of  $\text{Eu}^{3+}$ .

$$\tau = (A_1\tau_1^2 + A_2\tau_2^2)/(A_1\tau_1 + A_2\tau_2) \quad (2)$$

The values of  $\tau$  are calculated to decrease when the  $\text{Eu}^{3+}$  concentration increases; this indicates that energy transfer occurs from  $\text{Tb}^{3+}$  to  $\text{Eu}^{3+}$ , as expected. Furthermore, the energy transfer efficiency is calculated by the expression as follows:<sup>38</sup>

$$\eta_T = 1 - I_s/I_{s0} \quad (3)$$

where  $\eta_T$  represents the energy transfer efficiency, and  $I_s$  and  $I_{s0}$  represent the luminescence intensity of  $\text{Tb}^{3+}$  in the presence and absence of  $\text{Eu}^{3+}$ , respectively. The results of  $\eta_T$  are shown in Fig. 6(b). It can be found that the efficiencies from  $\text{Tb}^{3+}$  to  $\text{Eu}^{3+}$  increase with the increasing  $\text{Eu}^{3+}$  concentration, which can reach the maximum value of 83%. Therefore, the energy transfer from  $\text{Tb}^{3+}$  to  $\text{Eu}^{3+}$  ions is efficient to improve  $\text{Eu}^{3+}$  luminescence.

### 3.4 Energy transfer mechanism

The type of energy transfer should depend on either the exchange interaction or the multipolar interaction. It relies on the critical distance between the  $\text{Tb}^{3+}$  (sensitizer) and  $\text{Eu}^{3+}$  (activator), and the critical distance is expressed by the following formula:<sup>39</sup>

$$R_{\text{Tb-Eu}} = 2 \left[ \frac{3V}{4\pi x_c N} \right]^{1/3} \quad (4)$$

where  $V$  represents the cell volume,  $N$  is equal to the number of cations in the unit cell, and  $x_c$  is the total concentration of  $\text{Tb}^{3+}$  and  $\text{Eu}^{3+}$ . In this case,  $N = 4$  and  $V = 498.64 \text{ \AA}^3$ . The

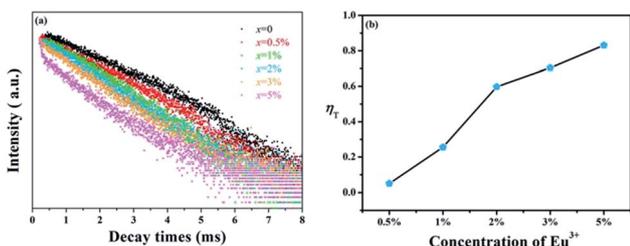

Fig. 6 (a) Decay curves of  $\text{Tb}^{3+}$  in  $\text{GdSr}_2\text{AlO}_5:2\%\text{Tb}^{3+}, x\%\text{Eu}^{3+}$  ( $x = 0, 0.5, 1, 2, 3,$  and  $5$ ). (b) Energy transfer efficiencies ( $\eta_T$ ) in  $\text{GdSr}_2\text{AlO}_5:2\%\text{Tb}^{3+}, x\%\text{Eu}^{3+}$  as a function of different  $\text{Eu}^{3+}$  concentrations.

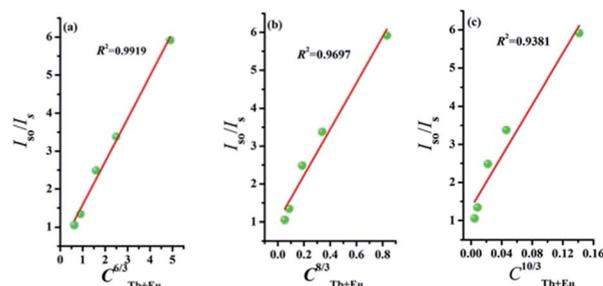

Fig. 7 Dependence of  $I_{s0}/I_s$  of  $\text{Tb}^{3+}$  on (a)  $C^{6/3}$ , (b)  $C^{8/3}$ , and (c)  $C^{10/3}$ .

corresponding distance is calculated to be more than  $5 \text{ \AA}$ , indicating that  $\text{Tb}^{3+} \rightarrow \text{Eu}^{3+}$  energy transfer would tend to be a multipolar interaction. On account of energy transfer mechanism for multipolar interaction, the following expression can be given:<sup>40,41</sup>

$$I_{s0}/I_s \propto C^{n/3} \quad (5)$$

where  $I_{s0}$  and  $I_s$  are the luminescence intensity of the sensitizer without and with activator.  $C$  represents the doping concentration of  $\text{Tb}^{3+}$  and  $\text{Eu}^{3+}$  ion. The values for  $n = 6, 8,$  and  $10$  correspond to dipole–dipole, dipole–quadrupole, and quadrupole–quadrupole interactions. Results are illustrated in Fig. 7. The best linear fit was obtained when  $n = 6$ , which confirmed energy transfer through dipole–dipole mechanism.

The detailed  $\text{Gd}^{3+} \rightarrow \text{Tb}^{3+}$ ,  $\text{Gd}^{3+} \rightarrow \text{Eu}^{3+}$ , and  $\text{Tb}^{3+} \rightarrow \text{Eu}^{3+}$  energy transfer processes are shown in Fig. 8. The electrons were excited from the  $^8\text{S}_{7/2}$  ground state to the  $^6\text{I}_J$  excited state of  $\text{Gd}^{3+}$  under  $275\text{ nm}$  excitation. Because the energy levels  $^5\text{D}_3$  of  $\text{Tb}^{3+}$  and  $^5\text{D}_1$  state of  $\text{Eu}^{3+}$  are lower than the  $^6\text{I}_J$  state of  $\text{Gd}^{3+}$  in the diagram, the energy transfer processes from  $\text{Gd}^{3+} \rightarrow \text{Tb}^{3+}$  and  $\text{Gd}^{3+} \rightarrow \text{Eu}^{3+}$  occur simultaneously. In addition, the electrons absorbing energy were excited from the  $^7\text{F}_6$  ground state to the  $^5\text{D}_3$  excited state of  $\text{Tb}^{3+}$ . The energy transfer process occurs between  $\text{Tb}^{3+}$  and  $\text{Eu}^{3+}$  activators since the  $^5\text{D}_3$  state of  $\text{Tb}^{3+}$  lies higher than the  $^5\text{D}_1$  state of  $\text{Eu}^{3+}$ . Then, the electrons from the excited state of  $^5\text{D}_3$  ( $\text{Tb}^{3+}$ ) and  $^5\text{D}_1$  ( $\text{Eu}^{3+}$ ) relaxed to  $^5\text{D}_4$  and  $^5\text{D}_0$ , respectively. Finally, green to red emission is yielded by electrons returning to their respective ground states.

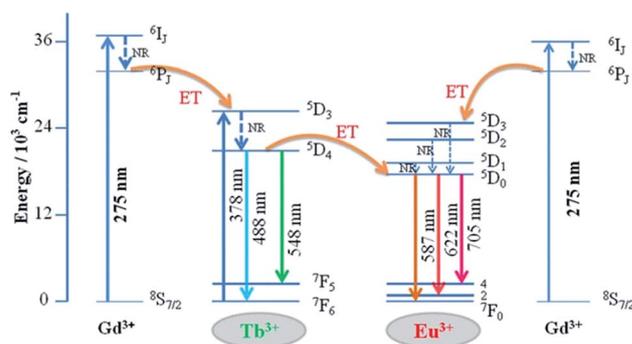

Fig. 8 Schematic of energy transfer from  $\text{Tb}^{3+}$  to  $\text{Eu}^{3+}$  in  $\text{GdSr}_2\text{AlO}_5$ .

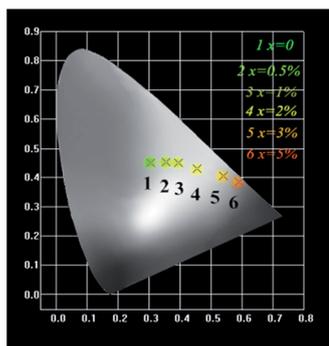

Fig. 9 CIE chromaticity diagram for  $\text{GdSr}_2\text{AlO}_5:2\%\text{Tb}^{3+}, x\%\text{Eu}^{3+}$  ( $x = 0, 0.5, 1, 2, 3, \text{ and } 5$ ) samples.

### 3.5 CIE chromaticity coordinate and QE

The Commission Internationale de L'Éclairage (CIE 1931) chromaticity coordinates of  $\text{GdSr}_2\text{AlO}_5:2\%\text{Tb}^{3+}, x\%\text{Eu}^{3+}$  phosphors under the excitation at 275 nm are presented in Fig. 9. The CIE coordinates shifted from (0.320, 0.466) to (0.574, 0.403) for the samples  $x = 0$  to  $x = 5\%$  correspond to green, yellow-green, and red. It is clear that the coordinate  $Y$  changes linearly with the  $X$ , the expression of which can be shown as below:

$$Y = 0.7541 - 0.6109X \quad (6)$$

The equation proves that the range of chromaticity coordinates can be obtained by adjusting the ratio of  $\text{Tb}^{3+}$  and  $\text{Eu}^{3+}$  mathematically. The as-prepared phosphor emits bright tunable visible light, implying its potential application in multicolor displays, and meets the requirement for application in  $n$ -UV LEDs.

For photo-luminescence application, the importance of quantum efficiency (QE) should be considered. According to the method described by De Mello *et al.*, QE can be calculated by the following equation:<sup>42</sup>

$$\eta_{\text{QE}} = \frac{\int L_{\text{S}}}{\int E_{\text{R}} - \int E_{\text{S}}} \quad (7)$$

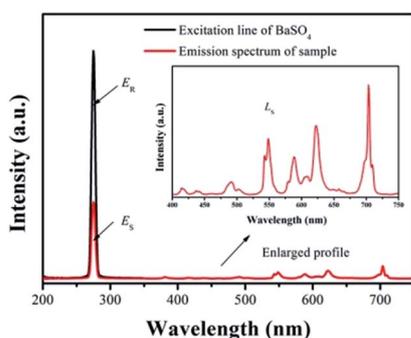

Fig. 10 Excitation line of  $\text{BaSO}_4$  and emission spectrum of the sample. Inset shows the magnification of the emission spectrum.

where  $L_{\text{S}}$  is the emission of the sample,  $E_{\text{S}}$  equals to the spectrum of the sample excited by the light, and  $E_{\text{R}}$  represents the spectrum of the excitation light without the sample. The results are listed in Fig. 10. Under 275 nm excitation, the calculated QE of  $\text{GdSr}_2\text{AlO}_5:2\%\text{Tb}^{3+}, 2\%\text{Eu}^{3+}$  is 78.5%, which demonstrates a high QE.

## 4. Conclusions

The  $\text{GdSr}_2\text{AlO}_5:\text{Tb}^{3+}, \text{Eu}^{3+}$  phosphors were prepared by a high temperature solid-state reaction method, and their luminescence properties were investigated in detail. Due to  $\text{REO}_8$  structure isolation, damping of the concentration quenching would occur. Energy transfer from  $\text{Gd}^{3+} \rightarrow \text{Eu}^{3+}$  and  $\text{Gd}^{3+} \rightarrow \text{Tb}^{3+}$  was found in the excitation spectrum. Moreover, the luminescence properties and the transient spectra confirmed the efficiency energy transfer from  $\text{Tb}^{3+}$  to  $\text{Eu}^{3+}$ . The mechanism it demonstrated is dipole-dipole interaction.  $\text{GdSr}_2\text{AlO}_5:\text{Tb}^{3+}, \text{Eu}^{3+}$  phosphors were able to provide multi-color emission from green, yellow, orange, and finally to deep red by the different ratios of  $\text{Tb}^{3+}/\text{Eu}^{3+}$ . Additionally, the QE can reach about 78.5%. All the results indicate that the series of  $\text{GdSr}_2\text{AlO}_5:\text{Tb}^{3+}, \text{Eu}^{3+}$  phosphors can be a candidate for color tunable luminescence materials used for  $n$ -UV LEDs.
