# Electrically tunable terahertz dual-band metamaterial absorber based on a liquid crystal

Zhiping Yin, Yujiao Lu, Tianyu Xia, Weien Lai, Jun Yang, Hongbo Lu   
and Guangsheng Deng \*

In this paper, a liquid crystal (LC) based tunable metamaterial absorber with dual-band absorption is presented. The proposed absorber is analysed both numerically and experimentally. The analysis shows that the two absorption peaks, originating from the new resonant structure, are experimentally detected at 269.8 GHz and 301.4 GHz when no bias voltage is applied to the LC layer. In order to understand the absorption mechanisms, simulation results for the surface current and power loss distributions are presented. Since liquid crystals are used as the dielectric layer to realize the electrically tunable absorber, a frequency tunability of 2.45% and 3.65% for the two absorption peaks is experimentally demonstrated by changing the bias voltage of the LC layer from 0 V to 12 V. Furthermore, the absorber is polarization independent and a high absorption for a wide range of oblique incidence is achieved. The designed absorber provides a way forward for the realization of tunable metamaterial devices that can be applied in multi-band detection and imaging.

## 1. Introduction

The terahertz (THz) waves ranging from 0.1 to 10 THz have attracted considerable attention from various researchers due to their emerging potential applications in imaging, sensing and spectroscopy.<sup>1–3</sup> Several efforts have been made for advancing the THz devices,<sup>4–6</sup> among which the THz absorber is believed to be a crucial component in developing THz detectors and sensors.

The concept of a metamaterial absorber (MA) was promoted by Landy *et al.*<sup>7</sup> The MAs have been widely investigated due to their low cost, small size and ultrathin thickness. Various structures, such as closed rings,<sup>8</sup> split rings<sup>9</sup> and cut-wire pairs,<sup>10</sup> have been proposed for MAs. Currently, the research is focused on absorbers intended for detecting and spectroscopic imaging applications. Therefore, tunable and multiband MAs are of great importance. One possible way to achieve frequency tunability of MA is to reconstruct the geometries, but it cannot be applied in the case of dynamic tuning. A tunable MA based on electrostatically actuated MEMS cantilever<sup>11</sup> or varactor loaded resonator<sup>12</sup> has been proposed. However, the fabrication of such structures is complicated. Recently, a progress toward the improvement of tune method has been made by changing the material properties. Graphene<sup>13–17</sup> and strontium titanate<sup>18,19</sup> have been proposed for tunable metamaterials. Nevertheless, the fabrication of these kinds of devices is still a big challenge at current state-of-the-art. Semiconductor<sup>20,21</sup>

and superconductor<sup>22,23</sup> were also adopted in tunable metamaterials, but the modulation of these devices requires harsh environment, which restricted their practical applications.

Liquid crystal (LC) is a promising candidate for tunable and dynamic metamaterials due to its voltage dependent birefringence. It has been widely employed to realize tunable metamaterials in recent years.<sup>24–26</sup> Compared to other active mediums, the LC has several advantages. Firstly, the LC based metamaterial is cost-effectiveness and easy-to-manufacture. Secondly, it can be operated at room temperature with low bias voltages. Shrekenhamer *et al.*<sup>27</sup> reported an electronically controlled MA based on the birefringence of LC cell at THz frequencies. Isić *et al.*<sup>28</sup> and Wang *et al.*<sup>29</sup> presented LC tunable THz absorbers with periodically arranged patch resonators. However, only one absorption peak frequency can be dynamically tuned for these works. To the best of authors' knowledge, LC based MA with multiple absorption peaks has been rarely reported. One of the main reasons is that the resonant structure of LC based MA is usually connected as a whole electrode. Hence, the existing multi-band absorber technologies by packing multiple discrete resonators within a unit cell are not suitable for LC based MAs.

In this paper, a polarization independent and tunable LC-based MA with two absorption peaks at THz frequencies is presented. Based on a new metamaterial unit cell structure, a LC and a dipole resonant mode are excited that are responsible for these two absorption peaks, respectively. The characteristics and the absorption mechanisms of the proposed MA are comprehensively investigated. Both the simulation and the measurement results have demonstrated that the two resonant

Academy of Photoelectric Technology, Hefei University of Technology, Hefei, 230009, China. E-mail: dgsh@hfut.edu.cn

frequencies can be dynamically tuned by adjusting the bias voltage of the LC layer.

## 2. Design of the structure

The schematic view of the proposed tunable absorber unit cell is shown in Fig. 1. The unit cell is formed by using two parallel quartz plates that are separated by a cavity filled with the liquid crystal. Meanwhile, a patterned copper layer and a copper ground plane are printed on the inner surface of each quartz plate. In summary, the quartz plates serve not only to support the metal layers, but also to encapsulate the LC layer.

The liquid crystal materials are composed of anisotropic molecules whose direction may change by an external electrical field. The orientation of the liquid crystal molecules and the permittivity of the LC layer along the electric field vector of the incident wave can be dynamically controlled by adjusting the bias voltage between the copper pattern layer and the metal ground. In order to control the orientation of the LC molecules in the absence of bias voltage, the inner surfaces of both copper layers are covered with polyimide (Pi) alignment layers. In the unbiased state ( $\epsilon_{\perp}$ ), the long axis of the molecules is aligned parallel to the surface of the quartz due to the static action of the polymer alignment layer. The bias voltage, applied across the biasing layers, rotates the LC molecules. This provides maximum permittivity ( $\epsilon_{\parallel}$ ), at the saturation state, while the direction is perpendicular to the cell walls. Therefore, the permittivity of the LC may be electronically varied between these two states, *i.e.*  $\Delta\epsilon_{\text{eff}} = \epsilon_{\parallel} - \epsilon_{\perp}$ , where the absorption frequency of the absorber may also be shifted.

Table 1 lists the dimensions of the unit cell structure. Besides, the pattern layer and the ground plate were made of 500 nm thick copper, while the quartz plates were considered as a dielectric material with relative permittivity of 3.78 and dielectric loss tangent of 0.02. In the simulation, the copper was treated as a Drude model with plasma frequency of  $1.12 \times 10^{16}$  rad  $s^{-1}$  and collision frequency of  $8.67 \times 10^{13}$  rad  $s^{-1}$ , respectively.<sup>30</sup> Moreover, the LC material was assumed to be S200, and its permittivity in the unbiased state ( $\epsilon_{\perp}$ ) and fully biased state ( $\epsilon_{\parallel}$ ) were set to be 2.47 and 3.06, respectively.<sup>31</sup>

The numerical time domain FDTD method is used to perform simulations, where the unit cell boundary conditions

Table 1 Structural dimensions of the designed absorber in Fig. 1

| Parameters               | $a$ | $R$ | $r$ | $b$ | $d$ | $s$ | $H_{q1}$ | $H_{q2}$ | $H_{LC}$ |
|--------------------------|-----|-----|-----|-----|-----|-----|----------|----------|----------|
| Values ( $\mu\text{m}$ ) | 410 | 190 | 155 | 20  | 20  | 12  | 500      | 1000     | 45       |

are applied in  $x$  and  $y$  directions. Since the proposed absorber has similar absorption characteristics for TE- or TM-polarized normal incident wave, the electromagnetic responses for the TE-polarized incident wave with electric field parallel to the  $x$ -axis are firstly investigated under the normal incidence.

The absorptivity of an absorber can be calculated by

$$A = 1 - |S_{11}|^2 - |S_{21}|^2 \quad (1)$$

where  $A$ ,  $S_{11}$ , and  $S_{21}$  are the absorptivity, the reflection coefficient, and the transmission coefficient, respectively. The transmission coefficient  $S_{21}$  is zero in this case because the thickness of the copper ground plate is much larger than its skin depth and the absorptivity can be regarded as  $A = 1 - |S_{11}|^2$ .

The simulated absorption spectrum of the proposed MA in the unbiased state ( $\epsilon_{LC} = 2.47$ ) is shown in Fig. 2. In the simulation, the loss tangent of LC layer is set to be 0.02. The figure shows that two distinct absorption peaks, named mode  $f_1$  and  $f_2$ , are located at 271 and 304.8 GHz with absorptivity of 97.1% and 95.3%, respectively. The simulation result provides a foundation for tuning of dual band absorption peaks with high absorptivity.

## 3. Simulated results and discussions

In order to demonstrate the intrinsic mechanism of the absorber, the surface current distributions on the copper pattern and the copper ground plane under TE-polarization are calculated corresponding to the two absorption peaks shown in Fig. 2. The simulated results are illustrated in Fig. 3.

For mode  $f_1$ , the surface current on the copper pattern mainly concentrates in the outer ring area as shown in Fig. 3(a). Moreover, the enlarged view shown in Fig. 3(b) indicates that an LC resonance mode is excited in each split-ring resonant area. Meanwhile, the surface current on the metal ground plane shown in Fig. 3(c) is reversed to that in Fig. 3(a), as the magnetic

Fig. 1 Schematic of a unit cell of the proposed tunable dual-band metamaterial absorber based on the liquid crystal. The geometry parameters are as follow:  $a = 410 \mu\text{m}$ ,  $R = 190 \mu\text{m}$ ,  $r = 155 \mu\text{m}$ ,  $b = 20 \mu\text{m}$ ,  $d = 20 \mu\text{m}$ ,  $s = 12 \mu\text{m}$ ,  $H_{q1} = 500 \mu\text{m}$ ,  $H_{q2} = 1000 \mu\text{m}$  and  $H_{LC} = 45 \mu\text{m}$ .

Fig. 2 Absorption spectrum of the proposed metamaterial absorber with permittivity of LC  $\epsilon_{LC} = 2.47$  under the normal incidence of TE-polarized wave.

Fig. 3 Simulated surface current distribution on: (a) copper pattern of mode  $f_1$ , (c) copper ground plane of mode  $f_1$ , (d) copper pattern of mode  $f_2$ , (f) copper ground plane of mode  $f_2$ , with (b) the enlarged view on copper pattern of mode  $f_1$  and (e) the enlarged view on copper pattern of mode  $f_2$ .

resonance is excited by the circulating currents between the two metallic layers. For mode  $f_2$ , the surface current on the patterned layer is concentrated in the connecting bars between the two adjacent units, which excites the dipole resonances as shown in Fig. 3(d) and (e). Similarly, the magnetic response for the second resonance mode is also excited by the reversed surface current between the patterned and the ground layers.

In order to further explore the absorption mechanism, the ohmic losses at the copper pattern layer and copper background, and the dielectric power loss densities in the quartz plate and the LC layer for the two peak absorption frequencies are calculated and the obtained results are shown in Fig. 4. It can be seen from the figure that the strength of the electric field determines the dielectric losses of the absorber in each dielectric layer, while the ohmic losses at the patterned copper layer are depended on the surface currents. Furthermore, it is observed that the most of the power losses is concentrated in

Fig. 4 Calculated results for peak absorption frequency. (a), (b), (e) and (f) distribution of the surface losses at copper pattern of mode  $f_1$ , copper background of mode  $f_1$ , copper pattern of mode  $f_2$ , and copper background of mode  $f_2$ , respectively. (c), (d), (g) and (h) distributions of the dielectric power loss densities of the quartz plate of mode  $f_1$ , the LC layer of mode  $f_1$ , the quartz plate of mode  $f_2$ , and the LC layer of mode  $f_2$ , respectively.

the LC layer, where it contributes 67.2% and 69.9% of total losses for the two absorption peaks, respectively.

It is well known that the reflection depends on impedance, and is defined by:

$$z(f) = \sqrt{\mu(f)/\epsilon(f)} = z_1 + iz_2 \quad (2)$$

where  $z_1$  and  $z_2$  represent the real and the imaginary impedance parts, respectively. In order to achieve the perfect impedance matching,  $z_1$  and  $z_2$  should tend to unity and to zero, respectively.

The retrieved impedance can be calculated by:<sup>32</sup>

$$z(f) = \sqrt{\frac{(1 + S_{11})^2 - S_{21}^2}{(1 - S_{11})^2 - S_{21}^2}} \quad (3)$$

The normalized input impedance is illustrated in Fig. 5. It can be seen that the normalized input impedances at the peak absorption frequencies of 271 and 304.8 GHz are  $0.881 + 0.177i$

Fig. 5 Response of the proposed structure for extracted normalized input impedance ( $z$ ).

and  $0.946 + 0.383i$ , respectively. Furthermore, the normalized input impedance is approximately equal to the free-space impedance at each peak absorption frequency, wherein a little reflection from the structure is introduced. Additionally, the transmission from the structure is also zero due to the existence of the metal ground plane. Consequently, the incident wave is trapped in the structure and the energy is dissipated through dielectric and ohmic losses.

Now let's focus on the frequency tunability of the proposed dual band metamaterial absorber. As mentioned above, the measured permittivity of LC material S200 in the unbiased state ( $\epsilon_{\perp}$ ) and the fully biased state ( $\epsilon_{\parallel}$ ) were 2.47 and 3.06, respectively. In this paper, the LC is treated as a homogenous isotropic material and the effective index of the aligned nematic LC is given by<sup>33</sup>

$$n_{\text{eff}} = \frac{n_e n_o}{\sqrt{n_e^2 \sin^2 \theta + n_o^2 \cos^2 \theta}} \quad (4)$$

where  $n_o$  and  $n_e$  represent the ordinary and the extra-ordinary indices, respectively. It is known that the LC is a nonmagnetic material. Thus, eqn (4) can be rewritten as:

$$\epsilon = \frac{\epsilon_{\perp} \epsilon_{\parallel}}{\epsilon_{\perp} \sin^2 \theta + \epsilon_{\parallel} \cos^2 \theta} \quad (5)$$

It can be concluded from eqn (5) that the LC permittivity is equal to  $\epsilon_{\perp}$  for the initial case ( $\theta = 0^\circ$ ), where the direction of the electric field vector in the LC layer is perpendicular to the LC molecular direction. With the increase of the bias voltage applied on the LC layer, the reorientation angle of the LC molecule gradually shifts towards the z axis and finally becomes parallel to the z axis ( $\theta = 90^\circ$ ), as the LC permittivity increases to  $\epsilon_{\parallel}$  at the fully-biased state.

The absorption spectra under the TE-polarized normal incidence excitation for the LC director angle values of  $\theta = 0^\circ$ ,  $30^\circ$ ,  $45^\circ$ ,  $60^\circ$ , and  $90^\circ$  (corresponding to the dielectric constants of liquid crystal of  $\epsilon_{\text{LC}} = 2.47, 2.595, 2.734, 2.888$  and  $3.06$ ) are calculated and shown in Fig. 6. The spectra demonstrate the

Fig. 6 Absorption spectra of the proposed absorber for different LC director angles  $\theta$  under the normal incidence of TE-polarized wave. The inset is the schematic view of LC molecular reorientation in the xz plane.

Fig. 7 Absorption spectra for different polarization angles under the normal incident wave. The electric field is changed by an angle  $\phi$  with respect to x-direction.

tunable performance of the proposed LC-based dual band absorber.

Fig. 6 shows two absorption peaks located at 271 and 304.8 GHz, for the initial alignment with LC molecular director parallel to the surface of the quartz. As the LC molecule is re-orientated from  $0^\circ$  to  $90^\circ$ , the two absorption peaks shift downwards to 261.5 and 290.8 GHz, accounting for 9.5 and 14 GHz frequency variation, respectively. From Fig. 6, the frequency tunability ( $f_{\text{mod}} = \Delta f/f_{\text{max}}$ ) for the two resonant modes is 3.51% and 4.59%, respectively. Moreover, the frequency tunability of mode  $f_2$  is relatively higher than mode  $f_1$ , which can be attributed to the higher sensitivity to substrate material of dipole resonant mode.

In order to validate the performance of the proposed absorber under different polarization angles, the responses for the polarization angle variation,  $\phi$ , under normal incidences are calculated and shown in Fig. 7. The figure shows that the proposed absorber is independent of wave polarization under normal incidence due to the structure symmetry.

The proposed structure is further studied theoretically under oblique incidence. For TM-polarized incident wave, the proposed structure maintains absorption above 0.75 up to  $60^\circ$  incident angle for both absorption peaks as shown in Fig. 8(a). With the increase of incident angle, the resonance frequency nearly remains the same for mode  $f_1$ . However, for mode  $f_2$ , the resonance frequency shows a blue shift. For TE-polarized incident wave, the proposed structure maintains absorption above 0.8 up to  $30^\circ$  of oblique incidence for both  $f_1$  and  $f_2$  modes. Moreover, from Fig. 8(b), it is interesting that with the increase of incident angle, more resonance modes with high resonant intensity are excited, providing a characteristic of multi-band absorption with high absorptivity over wide incident angles.

## 4. Experimental verification

In order to experimentally verify the proposed absorber, an array of overall size of  $2 \text{ cm} \times 2 \text{ cm}$ , with  $40 \times 40$  unit cells, was fabricated. The fabricated sample and the measurement setup

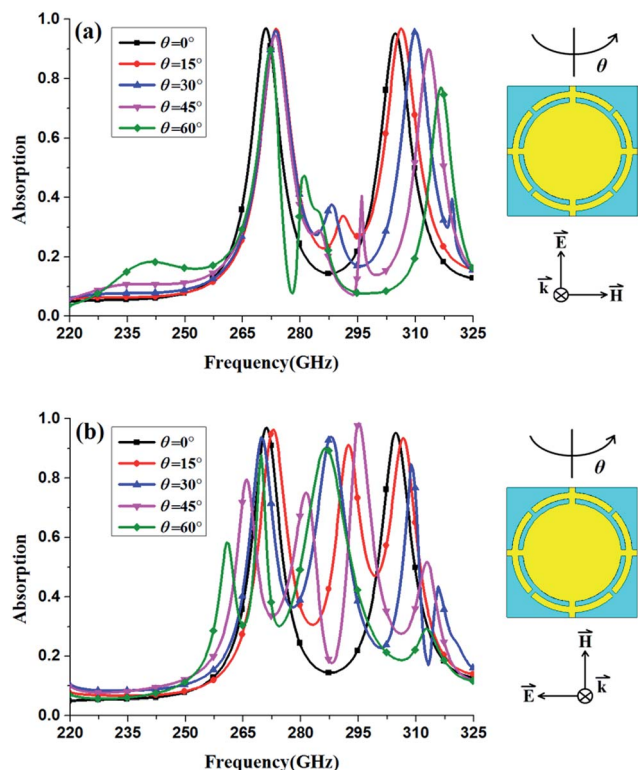

Fig. 8 Absorption spectra of the proposed metamaterial absorber for different incident angles: (a) for TM-polarized incident wave and (b) for TE-polarized incident wave.

are shown in Fig. 9. The setup contained an antenna connected to the Agilent N5224A vector network analyser *via* VNA extender VDI VNAX592, which was used for frequency range of 220–325 GHz. Moreover, a pair of THz lens were utilized to focus the THz

Fig. 9 Experimental demonstration of the proposed absorber. (a) Photograph of the fabricated sample with an enlarged view. (b) Experimental setup contained an antenna, a vector network analyser, a VNA extender, a function signal generator and a pair of THz lens.

beam, and an Agilent 33220A function signal generator was employed to produce the bias electronic field.

Fig. 10 illustrates the measured absorptions of the fabricated sample at unbiased and biased states under TM-polarization. The differences between the measured and the simulated results for the resonant frequencies and the absorptions are mainly attributed to the inaccurate size of the sample due to the fabrication precision and the inaccuracy of the measurement.

The frequency tunability of the absorber was obtained by measuring the absorption at different bias voltages as shown in Fig. 11. For mode  $f_1$ , as the bias voltage increases from 0 to 12 V, the resonance frequency shifts downwards from 269.8 to 263.2 GHz, with a frequency tunability of 2.45%. For mode  $f_2$ , a frequency tunability of 3.65% is achieved with the absorption frequency redshifts from 301.4 to 290.4 GHz. The measured frequency tunability of mode  $f_2$  is stronger than that of mode  $f_1$ , which is in agreement with the simulated results. However, it should be noticed that the measured frequency tunability is much lower compared to the simulated results with a frequency tunability of 3.51% and 4.59% for mode  $f_1$  and  $f_2$ , respectively. This is due to the fact that in experiment the liquid crystal molecules lying beyond the patterned electrode cannot be

Fig. 10 Simulated and measured absorption spectra at unbiased and biased states under the normal incidence of TE-polarized wave.

Fig. 11 Measured absorption spectra for different bias voltages under the normal incidence of TE-polarized wave. With the increase of bias voltage, resonant frequencies for both mode  $f_1$  and  $f_2$  show redshift.

efficiently re-orientated. Moreover, the liquid crystal cells lying under the patterned electrode cannot be fully re-orientated.<sup>34</sup> As a result, the measured performance of the absorber is worse than simulated results.

## 5. Conclusions

A THz tunable dual-band metamaterial absorber based on the liquid crystal is proposed in this paper. Based on a new metamaterial unit cell, the proposed structure experimentally provides two distinct absorption peaks at 269.8 and 301.4 GHz with absorptivity of 88.4% and 80.1%, respectively, when no bias voltage is applied. The absorption mechanism of the proposed structure is comprehensively investigated by the surface current distributions and the power loss distributions. The simulated results have demonstrated that the proposed absorber is polarization independent and is capable of providing high dual-band absorption for a wide range of incident angles under oblique incidence. The most important feature of the proposed absorber is that the dual-band absorption can be electrically tuned by simply adjusting the bias voltage of liquid crystal cavity from 0 to 12 V. Furthermore, the frequency tunability of 2.45% and 3.65% for the first and the second absorption peak, respectively, is experimentally demonstrated. The features of dual-band absorption and electric tunability validates that the proposed metamaterial absorber has significant potential applications in THz regime.
