# Photocatalytic activity of BiFeO<sub>3</sub>/ZnFe<sub>2</sub>O<sub>4</sub> nanocomposites under visible light irradiation†

B. Safizade, S. M. Masoudpanah, \* M. Hasheminasari and A. Ghasemi

Herein, BiFeO<sub>3</sub>/ZnFe<sub>2</sub>O<sub>4</sub> nanocomposites were synthesized *via* a glyoxylate precursor method using a two-pot approach. Phase evolution is investigated by X-ray diffraction and Raman spectroscopy, which confirm that no impurity phases are formed between BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub> following calcination at 600 °C. The specific surface area characterized by N<sub>2</sub> adsorption–desorption isotherms decreases from 30.56 to 13.13 m<sup>2</sup> g<sup>-1</sup> with the addition of zinc ferrite. In contrast, the magnetization increases from 0.28 to 1.8 emu g<sup>-1</sup> with an increase in the amount of ZnFe<sub>2</sub>O<sub>4</sub>. The composites show strong absorption in the visible region with the optical band gap calculated from the Tauc's plot in the range from 2.17 to 2.22 eV, as measured by diffuse reflectance spectroscopy. Furthermore, the maximum efficiency for the photodegradation of methylene blue under visible light is displayed by the composite containing 25 wt% ZnFe<sub>2</sub>O<sub>4</sub> due to the synergic effect between BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub>, as confirmed by photoluminescence spectroscopy.

## 1. Introduction

In recent years, scientific research has been focused on new visible light photocatalysts based on semiconductors to address the increasing environmental pollution and energy demands by efficient utilization of solar energy.<sup>1,2</sup> To date, various metal oxides (ZnO<sup>3</sup> and TiO<sub>2</sub><sup>4</sup>) and metal sulfides (ZnS<sup>5</sup>) have been studied to efficiently degrade harmful organic pollutants and for hydrogen production through water splitting under UV light irradiation.<sup>4</sup> However, the UV region spans only 5% of the entire solar spectrum, restricting their applications. As a result of band gap engineering improvement, composites can be fabricated by coupling two narrow band gap semiconductors, which have attracted considerable attention for the development of efficient visible light photocatalysts.<sup>6–8</sup>

Bismuth ferrite (BiFeO<sub>3</sub>), which has potential applications in sensors, actuators, and digital memory, is a well-known multi-ferroic material simultaneously possessing ferroelectric and ferromagnetic ordering at room temperature.<sup>9,10</sup> Furthermore, BiFeO<sub>3</sub> displays a distinct photovoltaic effect with an open circuit voltage of 0.8–0.9 V as a working solar device, which represents a new potential application.<sup>11,12</sup> Due to its relatively narrow band gap of 2.2 eV, BiFeO<sub>3</sub> has been considered as a possible visible light photocatalyst under solar light irradiation for the photodegradation of organic contaminants.<sup>13,14</sup> However, its quantum yield is poor due to the rapid recombination of the photogenerated electron–hole pairs that limits its

practical use in photocatalytic applications.<sup>15,16</sup> Therefore, many strategies have been developed to enhance the photocatalytic efficiency of BiFeO<sub>3</sub> by modifying the size and morphology of its particles, cation doping, and coupling with other semiconductors.<sup>17–19</sup> For instance, several semiconductors such as g-C<sub>3</sub>N<sub>4</sub>, carbon nanofiber, graphene, CuO and ZnO have been coupled with BiFeO<sub>3</sub> to improve its photogenerated electron–hole separation, thus enhancing its interfacial charge transfer the efficiency.<sup>6,20–27</sup>

Spinel magnetic zinc ferrite (ZnFe<sub>2</sub>O<sub>4</sub>) with a narrow band gap of 1.92 eV exhibits a significant photoresponse in the visible light region and has been utilized in gas sensors, catalysts and semiconductor photocatalysts.<sup>1</sup> Furthermore, the magnetic properties of ZnFe<sub>2</sub>O<sub>4</sub> can be used to recycle photocatalysts by the application of a magnetic field, making it an interesting product in the industrial photodegradation of organic pollutants.<sup>7,28</sup> To the best of our knowledge, there are no reports on the synthesis and application of BiFeO<sub>3</sub>/ZnFe<sub>2</sub>O<sub>4</sub> nanocomposites for pollutant degradation under visible light irradiation. Uniyal and Yadav only reported the dielectric and magnetic properties of BiFeO<sub>3</sub>/ZnFe<sub>2</sub>O<sub>4</sub> composites synthesized *via* the sol–gel method as a function of annealing temperature.<sup>29</sup>

Herein, we report the structure, microstructure, magnetic properties and photocatalytic performances of BiFeO<sub>3</sub>/ZnFe<sub>2</sub>O<sub>4</sub> composites synthesized *via* the glyoxylate precursor method. The optimum amount of ZnFe<sub>2</sub>O<sub>4</sub> is determined to maximize the photocatalytic activity of BiFeO<sub>3</sub> powder.

## 2. Experimental procedure

Starting materials of Fe(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O (>99%), Bi(NO<sub>3</sub>)<sub>2</sub>·5H<sub>2</sub>O (>99%), Zn(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O (>99%), 1,2-ethanediol (OH(CH<sub>2</sub>)<sub>2</sub>OH)

School of Metallurgy & Materials Engineering, Iran University of Science and Technology (IUST), Tehran, Iran. E-mail: masoodpanah@iust.ac.ir; Fax: +98 21 77240480; Tel: +98 21 77240540

† Electronic supplementary information (ESI) available: The UV-vis spectra and refined XRD patterns. See DOI: 10.1039/c7ra13380d

and nitric acid (HNO<sub>3</sub>, 68 wt%) of analytical grade were provided by Merck & Co.

BiFeO<sub>3</sub> powder was prepared *via* the glyoxylate precursor method in which the required amount of Fe(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O was dissolved in 1,2-ethanediol (ethylene glycol) and then added to 15 mL of 3 mol L<sup>-1</sup> nitric acid solution containing Bi(NO<sub>3</sub>)<sub>3</sub>·5H<sub>2</sub>O under magnetic stirring at 100 °C. The ethylene glycol : NO<sub>3</sub><sup>-</sup> (EG/NO<sub>3</sub>) molar ratio was set to 2.5 : 1. Evolving bubbles of brown nitrogen oxide (NO<sub>x</sub>) indicated the initiation of the redox reaction between the NO<sub>3</sub><sup>-</sup> anions and OH groups of diol. After drying at 130 °C, the precursor was calcined at 600 °C for 1 h in ambient air.<sup>30</sup> ZnFe<sub>2</sub>O<sub>4</sub> powder was produced by dissolving Zn(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O and Fe(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O in ethylene glycol under magnetic stirring at 100 °C. Once the NO<sub>x</sub> bubbles disappeared, the solution precursor was dried at 130 °C and then calcined at 600 °C for 1 h in air. BiFeO<sub>3</sub>/ZnFe<sub>2</sub>O<sub>4</sub> composites were synthesized *via* a two-pot approach in which the required amount of previously synthesized BiFeO<sub>3</sub> powder was added to the solution precursor of zinc ferrite, where the dried precursor was calcined at 600 °C for 1 hour.

Phase evolution was investigated using a PANalytical X'pert X-ray diffractometer (XRD) with monochromatic CuKα radiation. Raman analysis was performed on the powders using a WiTec Alpha 300R instrument (Nd:YAG laser source: λ = 532 nm and 0.7 MW power, and range: 100–900 cm<sup>-1</sup>). The morphology and microstructure of the powders were observed using a TESCAN Vega II scanning electron microscope (SEM). The specific surface areas of the as-prepared powders were determined according to the Brunauer–Emmett–Teller (BET) method with nitrogen adsorption at 77 K using a PHS-1020 instrument after degassing at 250 °C for 5 h. The Barrett–Joyner–Halenda (BJH) cumulative pore volume was calculated from the adsorption branch of the isotherms. The equivalent particle size was calculated based on the BET surface area as follows:

$$D_{\text{BET}} = \frac{6000}{\rho S_{\text{BET}}} \quad (1)$$

where,  $D_{\text{BET}}$  is the equivalent particle size (nm),  $\rho$  is the theoretical density and  $S_{\text{BET}}$  stands for the BET surface area (m<sup>2</sup> g<sup>-1</sup>). A vibrating sample magnetometer (Meghnatis Daghigh Kavir Kashan Co., Iran) with a maximum field of 10 kOe was employed to measure the magnetic properties at room temperature. UV-vis absorption spectra were recorded on a Shimadzu UV-vis-52550 spectrophotometer in the wavelength range of 300–800 nm. Room temperature photoluminescence spectra (PL) were obtained on a fluorescence spectrophotometer (F-4600, Hitachi, Japan) at an excitation wavelength of 210 nm.

The photocatalytic activity of the BiFeO<sub>3</sub>/ZnFe<sub>2</sub>O<sub>4</sub> nanocomposites was evaluated by the degradation of methylene blue (MB) in aqueous solution under visible light radiation. Two 100 W xenon lamps with a cutoff ultraviolet filter (λ = 420 nm) were introduced as the visible light source. In each experiment, 0.1 g of photocatalyst was added to 100 mL of methylene blue solution at a concentration of 15 mg L<sup>-1</sup>. In addition, the solution pH was adjusted to 2 by adding HCl to obtain the maximum MB adsorption on the catalyst surface,<sup>14</sup> as shown in

the ESI.† The suspension was stirred in the dark for 60 min to establish the adsorption/desorption equilibrium, then the solution was irradiated under visible light. At appropriate time intervals, about 5 mL of suspension was sampled, where the solid phase was separated from the solution *via* centrifugation at 4000 rpm for 20 min. The concentration of each degraded solution was monitored on a PG Instruments Ltd T80-UV/vis spectrophotometer.

### 3. Results and discussion

Fig. 1 shows the XRD patterns of the pure BiFeO<sub>3</sub>, pure ZnFe<sub>2</sub>O<sub>4</sub> and the BiFeO<sub>3</sub>-*x*ZnFe<sub>2</sub>O<sub>4</sub> composites. The indexed diffraction peaks of ZnFe<sub>2</sub>O<sub>4</sub> are (220), (311), (400), (422), (511), (440) and (533) which match well with the cubic spinel structure having the *Fd* $\bar{3}m$  space group and are in good agreement with the standard JCPDS card no. 22-1012. Pure BiFeO<sub>3</sub> shows indexed diffraction peaks corresponding to a rhombohedral phase with the *R*3*c* space group (JCPDS no. 86-1518), which indicates well crystallized BiFeO<sub>3</sub> nanoparticles were produced by the glyoxylate precursor method. However, some impurity Bi<sub>2</sub>Fe<sub>4</sub>O<sub>9</sub> phases (JCPDS card no. 42-0181) were also observed with BiFeO<sub>3</sub>. The chemical synthesis of BiFeO<sub>3</sub> typically leads to the formation of impurities, may be due to its chemical kinetics.<sup>31</sup> After compositing with 25 wt% ZnFe<sub>2</sub>O<sub>4</sub>, a weak diffraction peak at 2θ = 35.32° corresponding to the (311) reflection peak of ZnFe<sub>2</sub>O<sub>4</sub> appeared. With an increase in the zinc ferrite content, the diffraction peaks of ZnFe<sub>2</sub>O<sub>4</sub> became clearer and stronger, and the impurity peak disappeared. Furthermore, no impurity species were formed between BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub> during the calcination process, which indicates that ZnFe<sub>2</sub>O<sub>4</sub> was successfully loaded on the BiFeO<sub>3</sub> particles without destroying its crystal structure. The amount of BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub> phases

Fig. 1 XRD patterns of the BiFeO<sub>3</sub>-*x*ZnFe<sub>2</sub>O<sub>4</sub> composites as a function of ZnFe<sub>2</sub>O<sub>4</sub> content (*x*) (Bi<sub>2</sub>Fe<sub>4</sub>O<sub>9</sub>).

in the composites was calculated by Rietveld refinement, which is in agreement with the nominal values, as typically shown in the ESI.†

The Raman spectra of pure BiFeO<sub>3</sub>, pure ZnFe<sub>2</sub>O<sub>4</sub> and BiFeO<sub>3</sub>-*x*ZnFe<sub>2</sub>O<sub>4</sub> composites are presented in Fig. 2. In the spectrum of pure BiFeO<sub>3</sub>, the Raman active modes with A<sub>1</sub> and E symmetry can be summarized using the following irreducible representation  $\Gamma = 4A_1 + 9E$ .<sup>32</sup> The two peaks at 173 and 220 cm<sup>-1</sup> are assigned as A<sub>1</sub> modes, and the peaks at 286, 361 and 481 cm<sup>-1</sup> correspond to the E modes. Pure ZnFe<sub>2</sub>O<sub>4</sub> exhibited four peaks at 246, 327, 471 and 648 cm<sup>-1</sup>, which are assigned as the T<sub>2g</sub>(1), E<sub>g</sub>, T<sub>2g</sub>(2) and A<sub>1g</sub> modes for a cubic spinel structure, respectively.<sup>33</sup> The A<sub>1g</sub> mode of ZnFe<sub>2</sub>O<sub>4</sub> appears after 25 wt% ZnFe<sub>2</sub>O<sub>4</sub> was loaded, while the other modes were dominant at higher zinc ferrite contents. Moreover, the purity of the BiFeO<sub>3</sub>-*x*ZnFe<sub>2</sub>O<sub>4</sub> composites is confirmed by the absence of Raman modes of impurity phases.

The SEM images of pure BiFeO<sub>3</sub>, BiFeO<sub>3</sub>-25 wt% ZnFe<sub>2</sub>O<sub>4</sub>, BiFeO<sub>3</sub>-75 wt% ZnFe<sub>2</sub>O<sub>4</sub> and pure ZnFe<sub>2</sub>O<sub>4</sub> powders are displayed in Fig. 3. The quasi-spherical particles of BiFeO<sub>3</sub> (210 nm) are larger than the ZnFe<sub>2</sub>O<sub>4</sub> particles (80 nm). However, the BiFeO<sub>3</sub>-25 wt% ZnFe<sub>2</sub>O<sub>4</sub> composite is composed of plate-like particles. Furthermore, the average particle size decreases while the particle size distribution becomes rather uniform with an increase in ZnFe<sub>2</sub>O<sub>4</sub> content.

The N<sub>2</sub> adsorption-desorption isotherms of the BiFeO<sub>3</sub>-50 wt% ZnFe<sub>2</sub>O<sub>4</sub> composite are shown in Fig. 4. Table 1 also presents the specific surface area (*S*<sub>BET</sub>), equivalent particle size (*D*<sub>BET</sub>) and pore volume. The particle agglomerations show a typical type II isotherm according to the International Union of Pure and Applied Chemistry (IUPAC) classification.<sup>34</sup> The surface area of pure BiFeO<sub>3</sub> is 30.56 m<sup>2</sup> g<sup>-1</sup> and 13.13 m<sup>2</sup> g<sup>-1</sup> for pure ZnFe<sub>2</sub>O<sub>4</sub>. The higher specific surface area of pure BiFeO<sub>3</sub> is attributed to more gaseous products being formed during its synthesis,<sup>35</sup> as confirmed by its higher pore volume

(0.089 cm<sup>3</sup> g<sup>-1</sup>). The BJH pore size distribution is also depicted in the inset of Fig. 4. The pore size distribution of the BiFeO<sub>3</sub>-50 wt% ZnFe<sub>2</sub>O<sub>4</sub> composite powder exhibits a mesopore spreading of about 3–4 nm.

Fig. 5 illustrates the magnetization curves of the BiFeO<sub>3</sub>-*x*ZnFe<sub>2</sub>O<sub>4</sub> composites as well as the pure BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub> powders. The pure BiFeO<sub>3</sub> nanoparticles exhibit a ferrimagnetic response with the magnetization of 0.28 emu g<sup>-1</sup> at 10 kOe. However, the magnetization increases with an increase in zinc ferrite content since pure ZnFe<sub>2</sub>O<sub>4</sub> has a magnetization of 1.8 emu g<sup>-1</sup>. Bulk BiFeO<sub>3</sub> is known to show a G-type antiferromagnetic ordering with a linear field-dependence of magnetization, while the BiFeO<sub>3</sub> nanoparticles exhibit weak ferrimagnetism due to the interruption of the long-range antiferromagnetic order at the particle surface.<sup>36</sup> The bulk ZnFe<sub>2</sub>O<sub>4</sub> also has a normal spinel structure with antiferromagnetic behavior, while the ZnFe<sub>2</sub>O<sub>4</sub> nanoparticles exhibit a partially inverse spinel structure with some magnetic moment at room temperature.<sup>37</sup> A high surface-to-volume ratio in nanoparticles leads to more uncompensated spins from the surface, inducing an enhancement in magnetization. The BiFeO<sub>3</sub>-*x*ZnFe<sub>2</sub>O<sub>4</sub> composites show higher saturation magnetization than pure bismuth ferrite as a result of the higher magnetization in the zinc ferrite phase. This ferrimagnetism behavior can be exploited for the magnetic recovery of the photocatalyst after degradation.

The optical properties of the BiFeO<sub>3</sub>-*x*ZnFe<sub>2</sub>O<sub>4</sub> composites, as well as the pure BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub> powders were investigated *via* UV-vis diffuse reflectance spectroscopy, which are presented in Fig. 6. The absorption spectra show that the samples absorb a considerable amount of visible light. The direct optical band gap, *E*<sub>g</sub>, was determined using the equation  $(\alpha h\nu)^2 = A(h\nu - E_g)$ , where, *hν* is the photon energy in eV,  $\alpha$  is the absorption coefficient and *A* is a material constant,<sup>38</sup> as shown in the inset of Fig. 6. According to the Tauc plots, the band gaps for *x* = 0, 25, 50, 75 and 100 wt% were calculated to be 2.17, 2.03, 2.14, 2.15 and 2.22 eV, respectively. The absorption band of BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub> is attributed to the electronic transition from the valence band (O 2p orbital) to the conduction band (Fe 3d orbital) (O<sub>2p</sub><sup>2-</sup> → Fe<sub>3d</sub><sup>3+</sup>).<sup>39,40</sup> Clearly, the band gap of the BiFeO<sub>3</sub>-*x*ZnFe<sub>2</sub>O<sub>4</sub> photocatalysts gradually decreases with an increase in BiFeO<sub>3</sub>. In other words, by introducing ZnFe<sub>2</sub>O<sub>4</sub> into BiFeO<sub>3</sub>, the photocatalyst could absorb more visible light for the production of electron-hole pairs, which are favorable for photocatalytic reactions.

Fig. 7a shows the UV-vis spectra of the MB solution after different irradiation times in the presence of the BiFeO<sub>3</sub>-25 wt% ZnFe<sub>2</sub>O<sub>4</sub> composite. The main absorption peaks of MB molecules at 664 nm almost completely disappeared after about 120 min, which suggests the excellent photocatalytic activity of the BiFeO<sub>3</sub>-25 wt% ZnFe<sub>2</sub>O<sub>4</sub> composite. The photodegradation efficiency of MB dye by pure BiFeO<sub>3</sub>, pure ZnFe<sub>2</sub>O<sub>4</sub> and BiFeO<sub>3</sub>-*x*ZnFe<sub>2</sub>O<sub>4</sub> composites as a function of irradiation time are summarized in Fig. 7b.

Methylene blue was hardly degraded (~3%) by pure ZnFe<sub>2</sub>O<sub>4</sub> which exhibited very limited photolysis of MB under visible light irradiation. The low photocatalytic efficiency of pure

Fig. 2 Raman spectra of the BiFeO<sub>3</sub>-*x*ZnFe<sub>2</sub>O<sub>4</sub> composites.

Fig. 3 SEM images of (a) pure  $\text{BiFeO}_3$ , (b)  $\text{BiFeO}_3$ -25 wt%  $\text{ZnFe}_2\text{O}_4$ , (c)  $\text{BiFeO}_3$ -75 wt%  $\text{ZnFe}_2\text{O}_4$ , and (d) pure  $\text{ZnFe}_2\text{O}_4$  powders.

Fig. 4 Adsorption (filled symbol)–desorption (open symbol) isotherms of the  $\text{BiFeO}_3$ -50 wt%  $\text{ZnFe}_2\text{O}_4$  composite (the inset shows the pore size distribution).

$\text{ZnFe}_2\text{O}_4$  can be attributed to its low valence band potential and poor photoelectric conversion.<sup>7,41</sup> However, pure  $\text{BiFeO}_3$  can degrade 94.5% of MB after 2 hours of irradiation. The

Table 1 Dependence of specific surface area,  $S_{\text{BET}}$ , pore volume and equivalent particle size,  $D_{\text{BET}}$ , on  $\text{ZnFe}_2\text{O}_4$  content (x)

x	$S_{\text{BET}} (\text{m}^2 \text{g}^{-1})$	Pore volume ( $\text{cm}^3 \text{g}^{-1}$ )	$D_{\text{BET}} (\text{nm})$
$\text{BiFeO}_3$	30.56	0.089	23.6
25 wt%	28.42	0.086	27.9
50 wt%	19.75	0.072	44.8
75 wt%	18.97	0.069	52.6
$\text{ZnFe}_2\text{O}_4$	13.13	0.053	87.1

maximum MB photodegradation of  $\sim 97\%$  was observed for the  $\text{BiFeO}_3$ -25 wt%  $\text{ZnFe}_2\text{O}_4$  composite after 30 minutes of irradiation. The extraordinary photocatalytic efficiency of the  $\text{BiFeO}_3$ -25 wt%  $\text{ZnFe}_2\text{O}_4$  composite may be attributed to the formation of  $\text{BiFeO}_3$ - $\text{ZnFe}_2\text{O}_4$  heterojunctions, which promote the separation of photogenerated electron–hole pairs, thus enhancing the photocatalytic activity. However, the number of effective heterojunctions and thus separation efficiency strongly depend

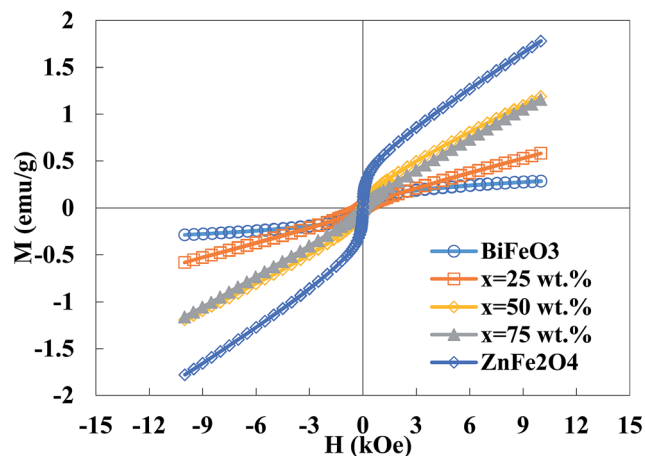

Fig. 5 Magnetization curves of the  $\text{BiFeO}_3$ - $x\text{ZnFe}_2\text{O}_4$  composites.

Fig. 6 UV-vis absorption spectra of the  $\text{BiFeO}_3$ - $x\text{ZnFe}_2\text{O}_4$  composites (the inset shows the Tauc plots).

on the content of the two components in the composite.<sup>20–22,42</sup> For the optimal content of 25 wt%  $\text{ZnFe}_2\text{O}_4$ , the most appropriate  $\text{BiFeO}_3/\text{ZnFe}_2\text{O}_4$  heterojunctions might be formed, which benefit the transfer and separation of photogenerated electrons and holes, as can be inferred from the PL spectra.

The suppression of charge recombination in  $\text{BiFeO}_3$  by pairing with  $\text{ZnFe}_2\text{O}_4$  can be confirmed by photoluminescence (PL) emission spectra, as presented in Fig. 8. As is known, the recombination of excited electrons and holes leads to PL emission, where a lower emission intensity indicates a decrease in recombination probability. Fig. 8 shows the PL emission spectra of the pure  $\text{BiFeO}_3$  and  $\text{BiFeO}_3$ -25 wt%  $\text{ZnFe}_2\text{O}_4$  photocatalysts at an excitation wavelength of 210 nm. The irradiative recombination process of self-trapped excitations results in an emission band at about 423 nm for pure  $\text{BiFeO}_3$ .<sup>43</sup> Clearly, the PL emission intensity decreases when zinc ferrite was added, which confirms that the coupling of  $\text{BiFeO}_3$  with  $\text{ZnFe}_2\text{O}_4$  results in an enhanced ability to capture photoinduced electrons in comparison with pure  $\text{BiFeO}_3$  and pure  $\text{ZnFe}_2\text{O}_4$ . The lower PL emission intensity of the  $\text{BiFeO}_3$ -25 wt%  $\text{ZnFe}_2\text{O}_4$

Fig. 7 (a) UV-vis spectra of MB solution in the presence of the  $\text{BiFeO}_3$ -25 wt%  $\text{ZnFe}_2\text{O}_4$  composite (the inset shows the photodegradation of MB), (b)  $C/C_0$  versus irradiation time for the photodegradation of MB dye under visible light irradiation by the  $\text{BiFeO}_3$ - $x\text{ZnFe}_2\text{O}_4$  nano-composites and (c) the removal efficiency of MB dye by adsorption and photodegradation.

photocatalyst benefits a delay in the recombination rate and, thus, higher photocatalytic activity.<sup>44–47</sup> In addition to the lower recombination rate of electron–hole pairs in the  $\text{BiFeO}_3$ -25 wt%  $\text{ZnFe}_2\text{O}_4$  catalyst, its higher specific surface area can also adsorb more MB dye on the exterior of its particles, as shown in Fig. 7c, hence facilitating the photodegradation of MB dye.

Fig. 8 Comparison of the PL spectra of pure BiFeO<sub>3</sub> and BiFeO<sub>3</sub>-25 wt% ZnFe<sub>2</sub>O<sub>4</sub> composite.

Based on the above structural characterizations and visible light photocatalytic tests, a possible mechanism for the photodegradation of MB by the BiFeO<sub>3</sub>/ZnFe<sub>2</sub>O<sub>4</sub> photocatalyst under visible light irradiation is proposed. Fig. 9 shows the band positions and transfer path of the photogenerated electron-hole pairs between BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub>. The conduction (CB) and valence (VB) band positions of BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub> at the point of zero charge were obtained from previous reports.<sup>15,48</sup> According to the general p-n heterojunction formation process,<sup>8</sup> the entire energy band of BiFeO<sub>3</sub> increases while that of ZnFe<sub>2</sub>O<sub>4</sub> decreases to achieve an equilibrium state of the Fermi energy level of BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub>. In this case, the conduction band and valence band of ZnFe<sub>2</sub>O<sub>4</sub> become higher than that of BiFeO<sub>3</sub>.

Under visible light irradiation, a high energy photon excites an electron from the valence band (VB) to the conduction band (CB) of BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub>. The photoinduced electrons in ZnFe<sub>2</sub>O<sub>4</sub> can easily transfer to BiFeO<sub>3</sub>, while the holes can

Fig. 9 Schematic for electron-hole transport at the interface of the BiFeO<sub>3</sub>-ZnFe<sub>2</sub>O<sub>4</sub> composite.

transfer to the VB of ZnFe<sub>2</sub>O<sub>4</sub> from the VB of BiFeO<sub>3</sub> conveniently with the help of the internal electric field formed at the interface between BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub>.<sup>20</sup> Therefore, the photogenerated electrons and holes are efficiently separated between BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub> reducing the electron-hole recombination in the composite photocatalyst, thus improving the photo-oxidation efficiency. The separated holes when moving to the surface of the BiFeO<sub>3</sub>/ZnFe<sub>2</sub>O<sub>4</sub> composite could react with H<sub>2</sub>O to form hydroxyl radicals, ·OH, which are powerful oxidative species for the direct oxidation of MB, leading to its decomposition.<sup>49,50</sup> However, the single electron reduction potential of O<sub>2</sub> ( $E_0(\text{O}_2/\text{O}_2^-) = -0.046$  eV) is less negative than the CB potentials, which confirms that the photoinduced electrons on the surfaces of BiFeO<sub>3</sub>/ZnFe<sub>2</sub>O<sub>4</sub> could not reduce O<sub>2</sub> to yield O<sub>2</sub><sup>-</sup> and could not take part in the photodegradation process.<sup>50,51</sup> The suitable ZnFe<sub>2</sub>O<sub>4</sub> content causes good dispersion in the catalyst, which benefits the formation of heterojunctions between the BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub> particles. Therefore, the high separation of charge carriers leads to the high photocatalytic activity of the BiFeO<sub>3</sub>-25 wt% ZnFe<sub>2</sub>O<sub>4</sub> photocatalyst.

## 4. Conclusions

A two-pot approach was used for the synthesis of BiFeO<sub>3</sub>/ZnFe<sub>2</sub>O<sub>4</sub> composites without any impurity species formed between BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub>. The particle size decreased from 210 nm for pure BiFeO<sub>3</sub> to 80 nm for pure ZnFe<sub>2</sub>O<sub>4</sub>. The pure BiFeO<sub>3</sub> nanoparticles exhibited a higher specific surface area than the pure ZnFe<sub>2</sub>O<sub>4</sub> nanoparticles, which may be due to the greater amount of released gaseous products. The magnetization of the BiFeO<sub>3</sub>/ZnFe<sub>2</sub>O<sub>4</sub> composites increased from 0.28 to 1.8 emu g<sup>-1</sup> with an increase in the ZnFe<sub>2</sub>O<sub>4</sub> content. The optical band gaps of composites initially decreased from 2.17 to 2.03 eV and then increased to 2.22 eV as a function of the amount of zinc ferrite. The maximum efficiency (~97%) for the photodegradation of methylene blue under visible light was exhibited for BiFeO<sub>3</sub>-25 wt% ZnFe<sub>2</sub>O<sub>4</sub> after 30 minutes irradiation due to the synergic effect between BiFeO<sub>3</sub> and ZnFe<sub>2</sub>O<sub>4</sub>.
