Deactivation by HCl of CeO₂–MoO₃/TiO₂ catalyst for selective catalytic reduction of NO with NH₃

Ye Jiang,^{id}*^a Mingyuan Lu,^a Shaojun Liu,^b Changzhong Bao,^a Guitao Liang,^a Chengzhen Lai,^a Weiyun Shi^a and Shiyuan Ma^a

The effect of HCl on a CeO₂–MoO₃/TiO₂ catalyst for the selective catalytic reduction of NO with NH₃ was investigated with BET, XRD, NH₃-TPD, H₂-TPR, XPS and catalytic activity measurements. The results showed that HCl had an inhibiting effect on the activity of the CeO₂–MoO₃/TiO₂ catalyst. The deactivation by HCl of the CeO₂–MoO₃/TiO₂ catalyst could be attributed to pore blockage, weakened interaction among ceria, molybdenum and titania, reduction in surface acidity and degradation of redox ability. The Ce³⁺/Ce⁴⁺ redox cycle was damaged because unreactive Ce³⁺ in the form of CeCl₃ lost the ability to be converted to active Ce⁴⁺ in the SCR reaction. In addition, a decrease in the amount of chemisorbed oxygen and the concentrations of surface Ce and Mo was also responsible for the deactivation by HCl of the CeO₂–MoO₃/TiO₂ catalyst.

1. Introduction

The selective catalytic reduction (SCR) of NO_x with NH₃ is an efficient technology for the removal of NO_x in flue gas from stationary sources.¹ V₂O₅–WO₃(MoO₃)/TiO₂ catalysts have been widely used in the last few decades.^{2,3} In recent years, great attention has been paid to develop environment-friendly vanadium-free catalysts for SCR applications mainly owing to the toxicity of vanadium.^{4,5} Cerium-based catalysts are regarded as promising candidates due to the high oxygen storage capacity and excellent redox properties of CeO₂.^{4,6,7} Many researchers have developed numerous cerium-based metal oxide catalysts, which possessed good SCR activity, such as MoO₃/CeO₂–ZrO₂,⁸ Cu–Ce–Ti oxide,^{6,9} Mn–Ce–Ti oxide,¹⁰ *etc.* Our group prepared a CeO₂–MoO₃/TiO₂ catalyst using a single step sol-gel method, which exhibited high SCR activity and resistance to 10% H₂O and 1000 ppm SO₂.¹¹ However, from the point of view of industrial applications, further studies are still required to clarify their adaptability to other components in flue gas from stationary sources, such as alkali (earth) metals, heavy metals, HCl, *etc.*

It is well known that HCl is widely present in the flue gas from coal-fired boilers and municipal solid waste (MSW) incinerators. The effect of HCl on SCR catalyst has been investigated by several researchers. Chen *et al.*¹² attributed the deactivation by HCl of V₂O₅/TiO₂ catalyst to the formation of volatile vanadium chlorides and NH₄Cl. Lisi *et al.*¹³ reported

that HCl suppressed the SCR activity of commercial V₂O₅–WO₃/TiO₂ catalyst due to the formation of new acid sites showing a lower activity compared to the original one. Yang *et al.*¹⁴ proposed that Cl could inhibit the adsorption of NH₃ and NO_x species, thereby leading to the deactivation of Ce/TiO₂. On the contrary, Hou *et al.*¹⁵ found that HCl had a positive effect on the catalytic activity of V₂O₅/AC catalyst at 150 °C. As for the effect of HCl on CeO₂–MoO₃/TiO₂ catalyst for the SCR of NO with NH₃, there were few reports to our knowledge till now.

In this work, the effect of HCl on CeO₂–MoO₃/TiO₂ catalyst was investigated for the SCR of NO with NH₃. A series of characterizations, including BET, XRD, XPS, NH₃-TPD and H₂-TPR, were performed to provide an insight into the substantial change in CeO₂–MoO₃/TiO₂ catalyst caused by HCl.

2. Experimental

2.1. Catalyst preparation

The CeO₂–MoO₃/TiO₂ catalyst was prepared by a single step sol-gel method as reported in our previous study.¹¹ The mass ratio of CeO₂ : MoO₃ : TiO₂ was 20 : 10 : 100. All chemicals used in the catalyst preparation were purchased from Sino-pharm Chemical Reagent Corp. (Shanghai, China). Except that titanium butoxide (TBOT) was chemically pure, the other reagents were of analytical grade. TBOT, anhydrous ethanol, deionized water, 65–68 wt% nitric acid, cerium nitrate hexahydrate (Ce(NO₃)₃·6H₂O) and ammonium molybdate tetrahydrate ((NH₄)₆Mo₇O₂₄·4H₂O) were mixed at a molar ratio of 1 : 35 : 19 : 2 : 0.1 : 0.1. After continuously stirred for 3 h at room temperature, the solution was kept at 80 °C for 24 h to form xerogel. The obtained xerogel were milled and sieved out,

^bState Key Laboratory of Clean Energy Utilization, Zhejiang University, 32 Zheda Road, Hangzhou 310027, China

followed by calcination at 500 °C for 5 h in static air. The catalyst was denoted as CMT.

The HCl-loaded CeO₂-MoO₃/TiO₂ catalysts were prepared by impregnation *via* incipient wetness with appropriate hydrochloric acid solution on CMT. The mixture was aged for 24 h and dried at 80 °C for 12 h. The HCl-loaded CeO₂-MoO₃/TiO₂ catalysts were denoted as CMT_x, where *x* represented the molar ratio of Cl and Ce.

2.2. Catalyst characterization

BET surface area, total pore volume and average pore diameter were measured by N₂ adsorption and desorption at -196 °C with ASAP2020-M (Micromeritics Instrument Corp.). Prior to the measurement, the sample was degassed in vacuum at 300 °C for 4 h.

X-ray diffraction (XRD) measurement was carried out with on a X'Pert PRO diffractometer (Panalytical Corp.) with Cu K α radiation at 40 kV and 40 mA.

X-ray photoelectron spectroscopy (XPS) data were obtained with a Thermo ESCALAB 250 spectrometer using monochromated Al K α X-rays ($h\nu = 1486.6$ eV) as a radiation source at 150 W. Sample charging effects were eliminated by correcting the observed spectra with the C 1s binding energy (BE) value of 284.6 eV.

Temperature programmed desorption of NH₃ (NH₃-TPD) and temperature programmed reduction of H₂ (H₂-TPR) were performed on a FINESORB-3010 chemisorption analyzer (FINETEC Instruments Corp.) with 0.1 g of the catalysts with a thermal conductivity detector (TCD). For NH₃-TPD, the sample was pretreated at 500 °C in He for 1 h. After cooled down, it was exposed in a 0.5% NH₃/He (30 mL min⁻¹) gas flow for 1 h, followed by flushing with He for 1 h. Finally, the sample was heated up to 700 °C with the rate of 10 °C min⁻¹ in He. H₂-TPR were carried out in the flow of H₂ (10%) in Ar (30 mL min⁻¹)

from room temperature to 800 °C with the heating rate of 10 °C min⁻¹.

2.3. SCR activity test

The activity measurements were carried out in a fixed-bed quartz reactor (i.d. = 8 mm) using 0.23 g catalyst with 60–100 mesh at atmospheric pressure in the temperature range of 150–500 °C. The feed gas contained 1000 ppm NO, 1000 ppm NH₃, 3 vol% O₂, 10% H₂O (when used), 500 ppm SO₂ (when used) and N₂ as balance gas. The total flow rate was 500 mL min⁻¹, corresponding to a gas hourly space velocity (GHSV) of 150 000 h⁻¹. The concentrations of NO, SO₂ and O₂ were continuously monitored by a gas analyzer (350 Pro, Testo). The concentrations of NO₂ and N₂O were recorded by a FT-IR gas analyzer (DX-4000, Gasmet). The NO conversion and N₂ selectivity of catalysts were calculated by:¹⁶

$$\text{NO conversion(\%)} = \frac{[\text{NO}]_{\text{in}} - [\text{NO}]_{\text{out}}}{[\text{NO}]_{\text{in}}} \times 100 \quad (1)$$

$$\text{N}_2 \text{ selectivity(\%)} = \left(1 - \frac{[\text{NO}_2]_{\text{out}} + 2[\text{N}_2\text{O}]_{\text{out}}}{[\text{NO}]_{\text{in}} - [\text{NO}]_{\text{out}}} \right) \times 100 \quad (2)$$

3. Results and discussion

3.1. NH₃-SCR performance

Fig. 1 shows the NH₃-SCR performance of the fresh and HCl-loaded CMT. It could be seen from Fig. 1(a) that the catalytic activity of CMT declined and its active temperature window was shortened with increasing HCl loadings in the temperature range of 150–500 °C. Furthermore, it seemed that the inhibiting effect of HCl on the SCR activity of CMT was more obvious below 300 °C. As for the N₂ selectivity, there was hardly a difference among the three samples at temperatures from

Fig. 1 SCR activity (a) and N₂ selectivity (b) of different samples as a function of reaction temperature. Reaction conditions: [NO] = [NH₃] = 1000 ppm, [O₂] = 3%, balance N₂, GHSV = 150 000 h⁻¹.

Fig. 2 Effect of H₂O on NO conversion over different samples. Reaction conditions: [NO] = [NH₃] = 1000 ppm, [O₂] = 3%, [H₂O] = 10%, balance N₂ and GHSV = 150 000 h⁻¹.

250 °C to 350 °C. The N₂ selectivity of CMT10 decreased slightly below 250 °C and at 350–450 °C in comparison with those of CMT and CMT5. It could be seen that HCl loadings had little influence on the N₂ selectivity of CMT.

The effect of H₂O on the SCR activities of the fresh and HCl-loaded CMT was investigated and the results are shown in Fig. 2. Compared with Fig. 1 and 2, it was found that CMT10 suffered much more serious deactivation than the other samples. The presence of H₂O suppressed the NO removal process over SCR catalysts by competing with NH₃ adsorption on the reaction sites or occupying the oxygen vacancies in active species.^{6,17,18} The existence of HCl on the surface of CMT was likely to aggravate the competitive adsorption of H₂O with NH₃ and the positioning of the oxygen vacancies in Ce species.

Fig. 3 Effect of H₂O and SO₂ on NO conversion for different catalyst samples as a function of reaction temperature. Reaction conditions: [NO] = [NH₃] = 1000 ppm, [O₂] = 3%, [H₂O] = 10%, [SO₂] = 500 ppm, balance N₂ and GHSV = 150 000 h⁻¹.

Fig. 3 displays the co-effect of H₂O and SO₂ on the SCR of NO with NH₃ over the fresh and HCl-loaded CMT. The presence of SO₂ and H₂O led to a rapid decrease in the SCR activities of the three samples to different extents. After about 4 hours, their activities became stable. It was clear that the resistance of CMT against SO₂ and H₂O declined with increasing the loadings of HCl. The deactivation by SO₂ of Ce-based oxide SCR catalysts was believed to result from the formation of sulfate species on their surface, including NH₄HSO₄, Ce(SO₄)₂ and Ce₂(SO₄)₃.^{17,19,20} In the presence of O₂, SO₂ and H₂O might react with NH₃ to produce NH₄HSO₄. NH₄HSO₄ could accumulate on catalyst surface and further cover active sites.¹⁹ On the other hand, SO₂ might combine with Ce species on catalyst surface in the presence of O₂ to form high thermally stable Ce(SO₄)₂ and Ce₂(SO₄)₃. They could hinder the Ce⁴⁺/Ce³⁺ redox cycle and inhibit the formation and adsorption of surface nitrate species.¹⁹ After SO₂ and H₂O were cut off from the feed gas, the NO conversions over CMT and CMT5 increased slightly, while no obvious change was observed in the NO conversion over CMT10. It indicated that there might exist NH₄HSO₄ on the surface of CMT and CMT5. After removing SO₂ and H₂O, unstable NH₄HSO₄ volatilized or decomposed. The deactivation of the three samples was largely caused by Ce(SO₄)₂ and Ce₂(SO₄)₃. The presence of HCl might promote the formation of the two sulfate species, thereby resulting in more serious deactivation of CMT10.

3.2. Characterization of catalysts

3.2.1 BET and XRD analysis. According to the BET results, it was found that the BET surface area of different samples decreased by the following order: CMT (99.06 m² g⁻¹) > CMT5 (88.76 m² g⁻¹) > CMT10 (81.49 m² g⁻¹). It was clear that the BET surface area of CMT decreased with increasing Cl loadings, which was consistent with the catalytic activity (as shown in Fig. 1). Fig. 4 shows the pore size distribution of the samples. It could be seen that the pore sizes of CMT increased with increasing Cl loadings while the pore volumes fell gradually. This meant that a portion of small mesopores might be blocked

Fig. 4 Pore size distributions of the catalyst samples.

Fig. 5 XRD patterns of the catalyst samples.

Fig. 6 XPS spectra of Ti 2p for the catalyst samples.

by chloride species. Wang *et al.*²¹ found the similar phenomena in the study on the effect of F or Cl on Mn/TiO₂ catalyst.

The XRD patterns of the fresh and HCl-loaded CMT are presented in Fig. 5. Only the diffraction peaks ascribed to anatase TiO₂ were detected, while the characteristic peaks of CeO₂ and MoO₃ were not observed. This demonstrated that the presence of HCl had no obvious impact on the dispersion of CeO₂ and MoO₃ on the surface of TiO₂. CeO₂ and MoO₃ were still highly dispersed and existed as amorphous or highly dispersed species in CMT. However, the intensity of the diffraction peaks due to anatase TiO₂ was found to increase with increasing Cl loadings. This meant that the presence of HCl served to weaken the interaction among CeO₂, MoO₃ and TiO₂, thereby resulting in the deactivation of CMT.

3.2.2 XPS analysis. The surface atomic concentrations of the catalyst samples are summarized in Table 1. The addition of HCl led to the decrease in the amount of reactive Ce and Mo atoms on the catalyst surface, which was in line with the catalytic activity. In addition, it was found that the measured Cl concentration on the catalyst surface was far lower than its nominal one. This might be due to its extraordinary high volatility.²²

As shown in Fig. 6, the binding energies of Ti 2p_{1/2} and Ti 2p_{3/2} in different catalysts were about 464.5 and 458.5 eV, respectively.²³ It suggested that Ti in CMT and CMT10 existed in its highest oxidation state (IV).²⁴ There was no significant change in the peak position among the two samples, but the intensities of both peaks increased after the introduction of Cl, which was

in accordance with the XRD results. This meant that there existed an interaction between HCl and Ti.

After a curve-fitting procedure in Fig. 7, the spectra of O 1s can be deconvoluted into two peaks. The peak at about 529.7–530.1 eV could be assigned to lattice oxygen (denoted as O_α) and the other one at about 531.1–531.4 eV could be related to chemisorbed oxygen (denoted as O_β) from oxide defects or hydroxyl-like groups.^{25,26} After treated by HCl, the O_β/O ratio decreased from 35.21% to 23.62%, which was in good agreement with the catalytic activity. O_β was considered to be more active in SCR reaction than O_α because of its higher mobility.²⁷ As a result, the SCR activity of CMT decreased after loading HCl.

The deconvoluted Ce 3d XPS results of the catalyst samples are shown in Fig. 8. The peaks labeled u, u', u'' and v, v', v'' are assigned to Ce⁴⁺, while u' and v' are attributed to Ce³⁺.^{28,29} The atomic ratio of Ce³⁺/Ce, calculated by the area of the corresponding peaks, increased from 31.81% to 34.76%. It indicated that the presence of HCl led to the increase in the amount of Ce³⁺ and the decrease in the amount of Ce⁴⁺ on the catalyst

Table 1 Surface element compositions of the catalyst samples determined by XPS

Sample	Surface atomic concentration (%)						
	O	Ti	Mo	Ce	Cl	O _β /O	Ce ³⁺ /Ce
CMT	66.53	27.71	3.09	2.68	—	35.21	31.81
CMT10	64.73	29.42	2.64	2.01	1.20	23.62	34.76

Fig. 7 XPS spectra of O 1s for the catalyst samples.

Fig. 8 XPS spectra of Ce 3d for the catalyst samples.

Fig. 10 XPS spectra of Mo 3d for the catalyst samples.

surface. It is widely accepted that Ce^{3+} can create a charge imbalance and form oxygen vacancies and unsaturated chemical bonds, which is helpful for the formation of chemisorbed oxygen on the catalyst surface.³⁰ However, it was unexpected that the increase in the amount of Ce^{3+} due to the presence of HCl did not promote the formation of chemisorbed oxygen. On the contrary, the amount of chemisorbed oxygen decreased. It might be supposed that not all Ce^{3+} species could act as a promoter on SCR activity.

Fig. 9 illustrates the XPS spectra of Cl 2p in CMT10. The peak appearing at 198.4 eV was assigned to Cl^- .³¹ According to the handbook of X-ray photoelectron spectroscopy,³² it could be inferred that CeCl_3 molecules might form on the surface of CMT10. It could be speculated that a fraction of CeO_2 might react with HCl according to the following reaction:

Fig. 9 XPS spectra of Cl 2p for the CMT10 sample.

The presence of HCl could result in the transformation of Ce^{4+} into Ce^{3+} . However, Ce^{3+} in the form of CeCl_3 lost the ability to be converted into active Ce^{4+} and was unreactive in SCR reaction. Therefore, the $\text{Ce}^{3+}/\text{Ce}^{4+}$ redox cycle was damaged. It is generally accepted that the redox pairs of $\text{Ce}^{3+}/\text{Ce}^{4+}$ on catalyst surface are vital for the SCR reaction over CeO_2 -based catalyst.³³ As a result, the catalytic performance of CMT decreased.

The Mo XPS profiles of catalyst samples are shown in Fig. 10. The binding energies of $\text{Mo } 3d_{5/2}$ and $\text{Mo } 3d_{3/2}$ were observed at 232.6 and 235.9 eV, and both spectra of the catalysts provide typical patterns for MoO_3 .³⁴ Regardless of the peak positions or intensities, there was no obvious difference between CMT and CMT10 catalyst samples. It suggested that the chemical environment of Mo^{6+} remained almost the same after the introduction of Cl. Unlike active Ce species, MoO_3 supported on TiO_2 was not to be highly active for the SCR reaction.¹⁷ MoO_3 primarily acted as a structural and chemical promoter rather than main active species. Compared with the Ce and Mo XPS results, it could be supposed that HCl preferentially reacted with active Ce species instead of Mo species. Consequently, Mo XPS curve was not changed in the presence of HCl.

3.2.3 NH_3 -TPD analysis. NH_3 -TPD analysis was performed to study the surface acidity of the catalyst samples and the results are presented in Fig. 11. Each catalyst sample contained a broad NH_3 desorption peak centered at about 200 °C, which could be assigned to the weakly adsorbed NH_3 on Brønsted acid sites.^{21,24} As for CMT, one small peak centered at about 600 °C was observed and could be attributed to the strongly adsorbed NH_3 on Lewis acid sites.³⁵ The presence of HCl resulted in the decrease in the NH_3 desorption peak area at low and high temperatures. Furthermore, the peak at high temperature shifted to higher temperatures. It indicated that the Brønsted acid sites and Lewis acid sites on the surface of CMT decreased, thereby inhibiting the adsorption of NH_3 species on the catalyst. As a result, HCl has a negative effect on the activity of CMT.

Fig. 11 NH_3 -TPD profiles of the catalyst samples.

Fig. 12 H_2 -TPR profiles of the catalyst samples.

3.2.4 H_2 -TPR analysis. Apart from the surface acidity of the catalyst, redox property is also another key factor which influences the performance of SCR catalyst. Fig. 12 illustrated the H_2 -TPR profiles of the catalyst samples. The TPR of the fresh CMT illustrated two overlapping reduction peaks, at 536 °C and 612 °C, indicating the co-reduction of surface Ce and well dispersed octahedral Mo species.^{36,37} After adding HCl, the peak at 612 °C disappeared while the peak at 536 °C moved to higher temperature. It was possible that the introduction of HCl make the two peaks overlap. Jin *et al.*³⁸ reported the similar phenomenon on $\text{CeO}_2/\text{TiO}_2$ catalyst with the modulation of HF. Nevertheless, the H_2 consumption decreased in the order: CMT > CMT5 > CMT10. It indicated that reducibility of CMT was weakened due to the presence of HCl. It was clear that HCl should be responsible for the strong inhibition in the catalytic activity of CMT.

4. Conclusions

In this work, the influence of HCl on the selective catalytic reduction of NO with NH_3 over $\text{CeO}_2\text{-MoO}_3/\text{TiO}_2$ catalyst was investigated. The experimental results showed that HCl had a negative effect on the SCR performance of $\text{CeO}_2\text{-MoO}_3/\text{TiO}_2$ catalyst. The presence of HCl led to pore blockage, weakened interaction among CeO_2 , MoO_3 and TiO_2 , reduction in surface acidity and degradation of redox ability. Though the amount of Ce^{3+} increased on the catalyst surface after adding HCl, Ce^{3+} in the form of CeCl_3 was not active in SCR reaction. The $\text{Ce}^{3+}/\text{Ce}^{4+}$ redox cycle was damaged. In addition, the concentration of surface Ce and Mo atoms and the amount of chemisorbed oxygen were found to decrease. All of these factors were responsible for the deactivation by HCl of CMT.
