# A vertical WSe<sub>2</sub>–MoSe<sub>2</sub> p–n heterostructure with tunable gate rectification†

Hailing Liu,<sup>†ab</sup> Sajjad Hussain,<sup>‡ab</sup> Asif Ali,<sup>ab</sup> Bilal Abbas Naqvi,<sup>ab</sup> Dhanasekaran Vikraman,<sup>id c</sup> Woonyoung Jeong,<sup>ab</sup> Wooseok Song,<sup>id d</sup> Ki-Seok An,<sup>id d</sup> and Jongwan Jung,<sup>id \*ab</sup>

Here, we report the synthesis of a vertical MoSe<sub>2</sub>/WSe<sub>2</sub> p–n heterostructure using a sputtering-CVD method. Unlike the conventional CVD method, this method produced a continuous MoSe<sub>2</sub>/WSe<sub>2</sub> p–n heterostructure. WSe<sub>2</sub> and MoSe<sub>2</sub> back-gated field effect transistors (FETs) exhibited good gate modulation behavior, and high hole and electron mobilities of  $\sim 2.2$  and  $\sim 15.1$  cm<sup>2</sup> V<sup>−1</sup> s<sup>−1</sup>, respectively. The fabricated vertical MoSe<sub>2</sub>/WSe<sub>2</sub> p–n diode showed rectifying *I*–*V* behavior with back-gate tunability. The rectification ratio of the diode was increased with increasing gate voltage, and was increased from  $\sim 18$  to  $\sim 1600$  as the gate bias increased from  $-40$  V to  $+40$  V. This is attributed to the fact that the barrier height between p-WSe<sub>2</sub> and n-MoSe<sub>2</sub> is modulated due to the back-gate bias. The rectification ratio is higher than the previously reported values for the TMDC p–n heterostructure grown by CVD.

## 1. Introduction

The two-dimensional transition metal dichalcogenides (TMDCs), in the form of MX<sub>2</sub> (M = metal and X = S, Se or Te), have recently received much attention for the study of physics in 2D materials and in layered structures.<sup>1–3</sup> In TMDCs, each M-atom (transition metal element) layer is enclosed within two X-atom (chalcogen element) layers and the atoms in the layers have hexagonally packed structures.<sup>1,3,4</sup> Every X–M–X atom arrangement is held together by van der Waals interactions. And due to the weak van der Waals interactions of each layer, it is possible to tune the band structure of the X–M–X atoms from an indirect ( $\sim 1.2$  eV) to a direct band gap ( $\sim 2.5$  eV) through heterogeneous integration. TMDCs exhibit good electrical properties<sup>1,3,5,6</sup> with high on/off ratios of  $\sim 10^8$ , and room-temperature mobility over 200 cm<sup>2</sup> V<sup>−1</sup> s<sup>−1</sup>.<sup>7–11</sup> Due to weak van der Waals forces between each stacking layer, 2D heterostructures can be easily produced by using mechanical transfer methods. Since p–n junctions are basic building blocks for electronic devices, and other optoelectronic devices,<sup>12–14</sup> the implementation of homo or hetero p–n junctions

is a key interest among researchers. Mechanical exfoliation is an easy way to produce p–n junctions; however, it is not suitable for mass production. Recently, many efforts have been made to apply chemical vapor deposition (CVD) to 2D heterostructures such as MoS<sub>2</sub>/graphene,<sup>15</sup> WS<sub>2</sub>/MoS<sub>2</sub>,<sup>16</sup> WS<sub>2</sub>/h-BN,<sup>17</sup> and n-MoS<sub>2</sub>/p-WSe<sub>2</sub>,<sup>18</sup> MoSe<sub>2</sub>–WSe<sub>2</sub>.<sup>18</sup> Nonetheless, the current rectification behavior of CVD-grown TMDC heterostructures is rarely reported and is poor.<sup>18</sup> Our group has been focusing on the synthesis of TMDCs by a sputtering-CVD method.<sup>19,20</sup> In this paper, we report a MoSe<sub>2</sub>/WSe<sub>2</sub> p–n heterostructure. A W film was sputtered and then selenized to form WSe<sub>2</sub>, and Mo was sputtered on the WSe<sub>2</sub> and selenized to form a vertical MoSe<sub>2</sub> (n)/WSe<sub>2</sub> (p) junction. Unlike the conventional CVD method, this method produces a continuous MoSe<sub>2</sub>/WSe<sub>2</sub> film. The WSe<sub>2</sub> and MoSe<sub>2</sub> back-gate field effect transistors (FETs) exhibited good gate modulation behavior, and high hole and electron mobilities of  $\sim 2.2$  and  $\sim 15.1$  cm<sup>2</sup> V<sup>−1</sup> s<sup>−1</sup>, respectively. The fabricated MoSe<sub>2</sub>/WSe<sub>2</sub> p–n diodes showed rectifying *I*–*V* behavior, and the forward diode current increased with increasing back-gate bias. The p–n diode with back-gate tunability showed a high gate-tunable rectification ratio varying from  $\sim 18$  to  $\sim 1600$  at different back-gate biases. This can be attributed to the fact that the barrier height between p-WSe<sub>2</sub> and n-MoSe<sub>2</sub> is modulated due to the back-gate bias. The rectification ratio is much higher than the previously reported value for the TMDC p–n heterostructure (MoS<sub>2</sub>/WSe<sub>2</sub>) grown by CVD.<sup>18</sup>

## 2. Experimental details

### 2.1 Synthesis of MoSe<sub>2</sub>/WSe<sub>2</sub>

Fig. 1 illustrates the overall growth scheme for the vertical MoSe<sub>2</sub>/WSe<sub>2</sub> heterostructure. The MoSe<sub>2</sub>/WSe<sub>2</sub> films were

**Fig. 1** Schematic of the  $\text{MoSe}_2/\text{WSe}_2$  heterostructure. (a) W was deposited onto the  $\text{SiO}_2/\text{Si}$  substrate. (b) A  $\text{WSe}_2$  film was formed *via* selenization. (c) Molybdenum (Mo) was deposited on the top of the  $\text{WSe}_2$ . (d) A  $\text{MoSe}_2/\text{WSe}_2$  heterostructure was formed *via* selenization. (e) The  $\text{MoSe}_2/\text{WSe}_2$  heterostructure with Al electrodes.

prepared by a RF magnetron sputtering system combined with a selenization process, using a W (99.9% pure) and a Mo (99.9% pure) target in an argon environment at room temperature. Initially a W thin film with a desired thickness was sputtered on a  $\text{SiO}_2/\text{Si}$  substrate through a metal shadow mask. Before sputtering, the chamber was evacuated by a turbomolecular pump to a vacuum at  $\sim 2 \times 10^{-6}$  Torr. During the film deposition, the Ar gas was maintained at 10 sccm, and the power was fixed at 150 W with a deposition time of 1200 s. Subsequently, the as-deposited W film was further put in the center of a furnace for selenization at 650 °C for 30 min to form a  $\text{WSe}_2$  film. The heating area for the selenium evaporation was fixed at 270 °C. The amount of selenium powder (0.5–0.8 g) used and the flow of Ar as a carrier gas were fixed for all the experiments. After the growth of the  $\text{WSe}_2$ , a Mo film was deposited on it. The sputtering conditions were the same for both films (W & Mo). The Mo/ $\text{WSe}_2$  film was again placed in the tube furnace for selenization annealing to form the  $\text{MoSe}_2/\text{WSe}_2$  heterojunction. The p–n junction area was defined by overlapped regions of two layers (Fig. 1). After the formation of the active area, Al (100 nm) was deposited on the top *via* e-beam evaporation.

## 2.2 Characterization techniques

All the samples were characterized using the latest analytical characterization techniques.  $\text{WSe}_2$ ,  $\text{MoSe}_2$  and  $\text{MoSe}_2/\text{WSe}_2$  heterostructure films were analyzed by using a Renishaw inVia RE04, with a 514 nm Ar laser, a laser spot-size of 1  $\mu\text{m}$ , laser power of 10 mW, and an exposure time of 30 s. A Si substrate with a Raman peak of 520  $\text{cm}^{-1}$  was used for calibration. X-ray photoelectron spectroscopy (XPS) (PHI 5000 Versa Probe, 25 W

Al  $K\alpha$ ,  $6.7 \times 10^{-8}$  Pa) was used for binding energy and elemental composition analysis. The crystallinity of the film was examined using in-plan X-ray diffraction (XRD, Rigaku) with Cu- $K\alpha$  radiation ( $\lambda = 54.178 \text{ \AA}$ ) operated at 50 kV and 300 mA current. FE-SEM (HITACHI S-4700) was used to demonstrate the morphological nature of the  $\text{WSe}_2$ ,  $\text{MoSe}_2$  and  $\text{MoSe}_2/\text{WSe}_2$  heterostructure films. The crystal structures of the resulting products were analysed using a JEOL-2010F TEM with the assistance of Gatan Digital Micrograph software (Gatan Microscopy Suite 2.0) for image acquisition and processing (FFT, R-FFT, etc.).

## 3. Results and discussion

Raman spectroscopy was used to characterize the formation of  $\text{WSe}_2$ ,  $\text{MoSe}_2$  and the  $\text{MoSe}_2/\text{WSe}_2$  heterostructures. For the  $\text{WSe}_2$  film, one main characteristic peak at 250.5  $\text{cm}^{-1}$ , assigned to the  $\text{E}_{2g}^1$  mode was observed.<sup>21</sup> On the other hand, for the  $\text{MoSe}_2$  film three characteristic phonon modes appeared in the Raman spectra: a sharp one at low wavenumber ( $\sim 242.2 \text{ cm}^{-1}$ ) associated with the out-of-plane vibration of Se atoms, and two broad ones at higher wavenumber ( $\sim 290.1 \text{ cm}^{-1}$ ), ( $\sim 352.0 \text{ cm}^{-1}$ ) corresponding to the  $\text{E}_{2g}^1$  and  $\text{B}_{2g}^1$  modes associated with the in-plane vibration of Mo and Se atoms.<sup>22–24</sup> In the Raman spectrum of the  $\text{MoSe}_2/\text{WSe}_2$  heterostructure, peaks

**Fig. 2** Raman spectra of  $\text{WSe}_2$ ,  $\text{MoSe}_2$  and the  $\text{MoSe}_2/\text{WSe}_2$  heterostructure films.

**Fig. 3** Top-down and cross-sectional SEM images. Top-down images of (a)  $\text{WSe}_2$ , (b)  $\text{MoSe}_2$  and (c) the  $\text{MoSe}_2/\text{WSe}_2$  heterostructure (d) cross-sectional image.

corresponding to both WSe<sub>2</sub> and MoSe<sub>2</sub> films appeared. In addition, there was no significant shift of the representative peaks for WSe<sub>2</sub> and MoSe<sub>2</sub> in the heterostructure. This supports that there was no serious alloying process of the WSe<sub>2</sub> and MoSe<sub>2</sub> encountered in the synthetic procedure, since the alloying process would be accompanied by peak shifts (Fig. 2).<sup>18</sup>

Scanning electron microscope (SEM) images reveal the formation of homogeneous MoSe<sub>2</sub> and WSe<sub>2</sub> thin films (Fig. 3a and b). Further, SEM confirms the existence of a dense array of grains for the MoSe<sub>2</sub>/WSe<sub>2</sub> heterostructure (Fig. 3c). The thicknesses of the MoSe<sub>2</sub> and WSe<sub>2</sub> films were ~160 nm and ~140 nm, respectively, estimated from the cross-sectional SEM image (Fig. 3d). The elemental mapping images of W, Mo and Se elements for the MoSe<sub>2</sub>/WSe<sub>2</sub> heterostructure are provided in the ESI in Fig. S1.† Transmission electron microscopy (TEM) characterization was further performed to analyse the surface of the MoSe<sub>2</sub>/WSe<sub>2</sub> heterostructure as shown in Fig. 4. The TEM images revealed that the film surface consisted of highly dense layers with a polycrystalline edge-exposed site structure.

X-ray photoelectron spectroscopy (XPS) was applied to examine the binding energies of WSe<sub>2</sub>, MoSe<sub>2</sub> and the MoSe<sub>2</sub>/WSe<sub>2</sub> heterostructure (Fig. 5a–d). The complete survey scans of WSe<sub>2</sub> and MoSe<sub>2</sub> are provided in Fig. S2.† From the WSe<sub>2</sub> film, the peaks at 32.2 and 34.4 eV were assigned to the doublet W 4f<sub>7/2</sub>

and W 4f<sub>5/2</sub> binding energies, respectively and the peak at 38 eV was assigned to W 5p<sub>3/2</sub> binding energy. The Se peaks at 54.7 and 55.1 eV (Fig. 5a and b) were indexed to be Se 3d<sub>5/2</sub> and Se 3d<sub>3/2</sub> respectively.<sup>21,25</sup> For the MoSe<sub>2</sub> film, Mo 3d<sub>3/2</sub> and 3d<sub>5/2</sub> core levels peaks were located at 231.1 and 228.0 eV, respectively. The peak of Se around 54.0 eV can be divided into Se 3d<sub>5/2</sub> and Se 3d<sub>3/2</sub> with peak positions at 54.6 and 55.2 eV, respectively<sup>26,27</sup> (Fig. 5c and d). The XPS survey scan of the MoSe<sub>2</sub>/WSe<sub>2</sub> heterostructure revealed the presence of W, Mo and Se elements (Fig. S3†).

XPS depth profile analysis was performed to investigate the typical WSe<sub>2</sub>/MoSe<sub>2</sub> heterostructure. A 1 keV Ar ion beam was used for continuous etching of the WSe<sub>2</sub>/MoSe<sub>2</sub> heterostructure in the direction from top to bottom. Fig. 6a–c show the XPS depth profile spectra for the W, Mo and Se binding energies. The Mo peak intensities were decreased and the W peak intensities were increased with etching time, whereas Se peak intensities were slightly varied due to the presence of Se in both structures. These findings confirm the heterostructure formation without diffusion or alloy formation. The Mo atomic concentration from the top-layer of MoSe<sub>2</sub> drastically decreased, although the W atomic concentration from the bottom-layer of WSe<sub>2</sub> linearly increased up to 120 s of etching time as shown in Fig. 6d. The cross sectional SEM image of the heterostructure is also evidence of our dual layered structure.

We characterized the electrical transport properties of WSe<sub>2</sub> and MoSe<sub>2</sub> back-gated field effect transistor (FET) devices (Fig. 7a and b). Transfer characteristics of source-drain current (*I*<sub>ds</sub>) versus back-gate voltage (*V*<sub>gs</sub>) were measured for WSe<sub>2</sub> and MoSe<sub>2</sub> FETs. The WSe<sub>2</sub> and MoSe<sub>2</sub> devices presented p-type and n-type behavior under back-gate biasing (constant bias, *V*<sub>ds</sub> = 1 V), respectively, similar to the earlier reports by other research group.<sup>22,28</sup> The field-effect mobility was extracted from the slope of  $\Delta I_{ds}/\Delta V_{gs}$  fitted to the linear region of the transfer curves using the following equation

$$\mu = \frac{L}{WC_{ox} V_{ds}} \frac{\Delta I_{ds}}{\Delta V_{gs}} \quad (1)$$

Fig. 4 (a and b) TEM images of the MoSe<sub>2</sub>/WSe<sub>2</sub> heterostructure.

Fig. 5 XPS spectra: (a) W 4f and (b) Se 3d binding energies for WSe<sub>2</sub>. (c) Mo 3d, 4f and (d) Se 3d binding energies for MoSe<sub>2</sub>.

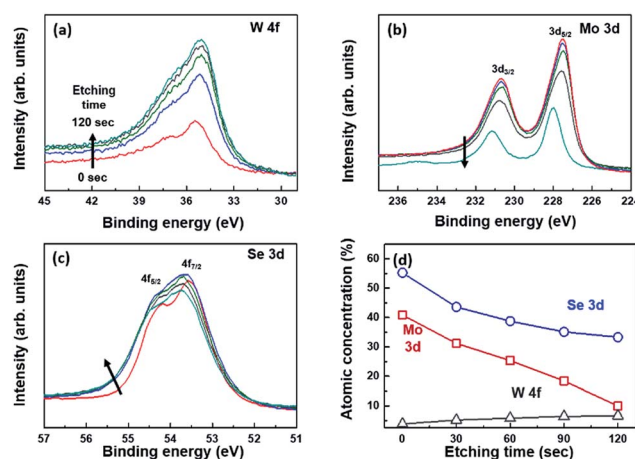

Fig. 6 XPS depth profile spectra of (a) W 4f, (b) Mo 3d, and (c) Se 3d binding energies and (d) their atomic concentration variations in terms of etching time for the MoSe<sub>2</sub>/WSe<sub>2</sub> heterostructure.

Fig. 7 Electrical output and transfer curves of the WSe<sub>2</sub> and MoSe<sub>2</sub> devices. (a and b)  $I_{ds}$ - $V_{gs}$  of the WSe<sub>2</sub> FET at fixed  $V_{gs} = 1$  V;  $I_{ds}$ - $V_{ds}$  of the WSe<sub>2</sub> FET at  $V_{ds}$ : 20 V to -40 V (inset). (c and d)  $I_{ds}$ - $V_{gs}$  of the MoSe<sub>2</sub> FET at  $V_{gs} = 1$  V;  $I_{ds}$ - $V_{ds}$  of the MoSe<sub>2</sub> FET at  $V_{ds}$ : 20 V to -40 V (inset).

where  $W$  is the width of the channel (10  $\mu\text{m}$ ),  $L$  is the length of the channel (10  $\mu\text{m}$ ),  $C_{ox}$  is the capacitance per unit area of the gate dielectric with 300 nm thickness ( $1.15 \times 10^{-8} \text{ F cm}^{-1}$ ),  $V_{ds}$  is the applied drain voltage and  $\Delta I_{ds}/\Delta V_{gs}$  is the slope of the linear part of the transfer plot ( $I_{ds}$ - $V_{gs}$ ) or the transconductance. The estimated field-effect mobility values of WSe<sub>2</sub> and MoSe<sub>2</sub> FETs are  $\sim 2.2 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$  and  $\sim 15.1 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ , respectively and on/off current ratios are  $\sim 3\text{--}6 \times 10^5$ . The linear  $I_{ds}$ - $V_{ds}$  characteristics of both WSe<sub>2</sub> and MoSe<sub>2</sub> devices exhibited good ohmic contacts and there was an absence of significant charge injection barriers. Compared to the subthreshold characteristics, MoSe<sub>2</sub> had a better subthreshold swing than WSe<sub>2</sub>. Electrical properties of the MoSe<sub>2</sub>/WSe<sub>2</sub> heterostructure film were also measured. Voltages were applied to the metal pads of the p-type WSe<sub>2</sub> and the n-type MoSe<sub>2</sub> with changing back-gate bias. Fig. 8a shows the linear  $I$ - $V$  curves of the stacked MoSe<sub>2</sub>/WSe<sub>2</sub> p-n junction at various back-gate voltages. The drain voltage in

Fig. 8 Linear scale and log scale plots of  $I$ - $V$  characteristics of the MoSe<sub>2</sub>/WSe<sub>2</sub> heterojunction (a) linear scale plots of  $I$ - $V$ . (b) Log scale  $I$ - $V$  with different back-gate voltages  $V_{gs}$  (c) rectification ratio ( $I_{ds}@V_{ds} = 1 \text{ V} / I_{ds}@V_{ds} = -1 \text{ V}$ ) as a function of back-gate voltage  $V_{gs}$ .

Fig. 8a is the voltage applied to p-WSe<sub>2</sub> with respect to n-MoSe<sub>2</sub>. Rectifying  $I$ - $V$  characteristics were observed from the p-n junction between n-type MoSe<sub>2</sub> and p-type WSe<sub>2</sub>. The current in Schottky barrier diodes can be expressed as

$$I = I_0 \left( e^{\frac{qV}{nkT}} - 1 \right) \quad (2)$$

where,  $I_0$  is the saturation current,  $k$  is the Boltzmann constant,  $T$  is the absolute temperature,  $q$  is the elementary electric charge, and  $V$  is the applied voltage. The saturation current  $I_0$  is expressed as

$$I_0 = AA^*T^2 e^{-\frac{q\Phi_b}{kT}} \quad (3)$$

where,  $A$  is the device area,  $A^*$  is the effective Richardson constant, and  $\Phi_b$  is the barrier height. The ideality factor of the Schottky diode is extracted from the slope of the linear region of the  $\ln I$ - $V$  characteristic and is expressed as

$$n = \left[ \frac{q}{kT} \right] \left[ \frac{dV}{d(\ln I)} \right] \quad (4)$$

The ideality factor varies with back-gate bias, and is  $\sim 1.5$  at a low bias range at  $V_{gs} = 40 \text{ V}$ . The forward current is also increased upon increasing the back-gate voltage. The back-gate voltage controls the charge carrier densities of the electrons and holes in n-MoSe<sub>2</sub> and p-WSe<sub>2</sub>. Since the bottom layer is p-type WSe<sub>2</sub> and the top layer is n-type MoSe<sub>2</sub>, it is expected that hole concentration in WSe<sub>2</sub> decreases with increasing back-gate bias, while the top n-type MoSe<sub>2</sub> is less affected. Since the p-n junction is mainly composed of a vertical n-MoSe<sub>2</sub>/p-WSe<sub>2</sub> junction and partly of a lateral side junction (the vertical junction area is much larger than the lateral side junction), the carrier concentration in the p-WSe<sub>2</sub> layer is readily modulated by the back-gate bias, while the electrons in the top MoSe<sub>2</sub> is less affected by screening due to the bottom WSe<sub>2</sub> layer. Therefore, upon increasing the back-gate bias, the barrier height between WSe<sub>2</sub> and MoSe<sub>2</sub> decreases, and in turn increases the forward current. Fig. 8b is a plot of logarithmic  $I$  versus linear  $V$ .

The reverse current also increases with increasing back-gate voltage. This is also due to the lowered barrier height between p-WSe<sub>2</sub> and n-MoSe<sub>2</sub>. Fig. 8c shows the rectification ratios of the diode. The rectification ratio is defined as the forward current at 1 V anode bias (the p-WSe<sub>2</sub> voltage with respect to the n-MoSe<sub>2</sub> voltage) versus reverse current at -1 V anode bias. It is observed

Fig. 9 Energy band diagram of n-MoSe<sub>2</sub> and p-WSe<sub>2</sub> at (a) 0, (b) negative and (c) positive back-gate voltage.

that the rectification is modulated by the back-gate voltage. The rectification ratio of the diode is increased from  $\sim 20$  to  $\sim 1800$  as the back-gate bias is varied from  $-40$  V to  $+40$  V as shown in Fig. 8c. This value is much higher than the reported value ( $\sim 150$ ) for the TMDC p-n heterostructure ( $\text{MoS}_2/\text{WSe}_2$ ) grown by CVD.<sup>18</sup>

The energy band diagram (Fig. 9) reveals the formation of a built-in potential in the heterojunction p- $\text{WSe}_2$ /n- $\text{MoSe}_2$ , in which the conduction band ( $E_c$ ) of  $\text{WSe}_2$  lies above that of  $\text{MoSe}_2$ . The built-in potential is produced due to the formation of a depletion region at the interface. This barrier height is increased at negative gate bias as energy levels in  $\text{WSe}_2$  are shifted towards higher energy levels (Fig. 9b). Current is increased when the positive gate bias is applied (Fig. 9c). Positive gate bias leads to a decrease of the electron barrier and the energy levels in  $\text{WSe}_2$  shift towards lower energy, which results in the reduction of the barrier between the p- and n-regions and increased the forward current.

## 4. Conclusions

We fabricated a  $\text{MoSe}_2/\text{WSe}_2$  p-n heterostructure using a sputtering-CVD method. The  $\text{WSe}_2$  and  $\text{MoSe}_2$  back-gated field effect transistors (FETs) exhibited good gate modulation behavior, and high hole and electron mobilities of  $\sim 2.2$  and  $\sim 15.1 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ , respectively. The fabricated  $\text{MoSe}_2/\text{WSe}_2$  p-n diodes exhibited gate-tunable rectifying  $I$ - $V$  characteristics. The rectification ratio of the p-n diode is increased with an increase in the gate voltage, and it is increased from  $\sim 18$  to  $\sim 1600$  as the gate bias is increased from  $-40$  V to  $+40$  V. This is attributed to the fact that the barrier height between p- $\text{WSe}_2$  and n- $\text{MoSe}_2$  is lowered due to the back-gate bias. The rectification ratio is much higher than the previously reported value for the TMDC p-n heterostructure ( $\text{MoS}_2/\text{WSe}_2$ ) grown by CVD.
