# Transition metal free, late-stage, regiospecific, aromatic fluorination on a preparative scale using a KF/crypt-222 complex†

Jimmy Erik Jakobsson <sup>\*a</sup> and Patrick Johannes Riss<sup>abc</sup>

We herein report the development of a convenient, regioselective, aromatic fluorination method of hypervalent iodonium ylides for synthesising fluoro-arenes on a preparative scale. This transition metal free, nucleophilic methodology provides good yields for sterically hindered substrates, irrespective of activation. The methodology simplifies reference synthesis for PET imaging.

Fluorinated organic molecules are of importance in crop protection and materials science and as pharmaceuticals due to their unique properties. Aryl fluorides are of particular interest in medicinal chemistry<sup>1</sup> due to their exceptional metabolic stability. For instance, fluorine is often used as a tool in medicinal chemistry for fine tuning the physicochemical properties of drug candidates in late stage development.<sup>2</sup> The presence of fluorine in drug molecules also allows for further investigation by positron emission tomography (PET) *via* incorporation of radioactive fluorine-18 (<sup>18</sup>F, *t*<sub>1/2</sub> = 110 min). The radionuclide <sup>18</sup>F is ideal for PET imaging, due to its very advantageous half-life and decay characteristics.<sup>3</sup>

Current late stage fluorination methodologies of arenes and heteroarenes are often based on expensive, potentially toxic transition-metals (Ag/Cu,<sup>4</sup> Cu,<sup>5</sup> Ni,<sup>6</sup> Pd<sup>7</sup>) or involve electrophilic fluorination reagents and may necessitate the use of additional, advanced equipment such as gloveboxes to achieve more anhydrous conditions. Therefore a mild, versatile and selective fluorination methodology that utilises cheap nucleophilic fluoride for late stage formation of fluoroarenes is highly sought after.<sup>8</sup> In addition, we aim to progress into greener, more environmentally friendly alternatives with easy to handle chemicals by moving away from toxic transition metals. In order to be independent from classical substrates of the S<sub>N</sub>Ar reaction, we chose hypervalent iodine species as fluorination precursors. The hypervalent iodine chemistry utilises the plethora of well-investigated and described iodination protocols and iodonium ylide forming reactions as a basis for constructing aryl fluorides. Such a method would also bridge the gap

between preparative organic chemistry and radiochemistry thus applying the same precursor for synthesising both radiotracer and reference compound in the last step (Scheme 1). Radio-fluorination of iodonium ylides is well described,<sup>9</sup> however in radiochemistry reagent stoichiometry is vastly different with the precursor used in >1000 fold excess over no carrier added fluorine-18, the limiting reagent.<sup>‡</sup> For the methodology to be useful on preparative scale the precursor should ideally be the limiting reagent and a cheap fluorination reagent such as KF, CsF or TBAF used in excess. We therefore employed a reverse translational approach developing a preparative organic protocol for the fluorination reaction under stoichiometric conditions. Through this new protocol, PET chemistry is merged with preparative organic chemistry enabling use of iodonium ylides as versatile fluorination precursors.

Electron deficient substrates can undergo a classical S<sub>N</sub>Ar reaction<sup>10</sup> therefore for this investigation we decided to use 2-fluoroanisole as model compound since it is both sterically hindered and electron rich and therefore challenging to produce. All reactions were performed without access to glove box using standard equipment and precautions to allow for good reproducibility in between labs. We began by screening the most common nucleophilic fluorination reagents in organic, dipolar aprotic solvents (Table 1).

Caesium fluoride produced mere trace amounts of product (2), possibly owing to its high hygroscopicity and difficulty of excluding moisture (Table 1, entry 1). Tetrabutylammonium fluoride trihydrate yielded a higher conversion (2, 9%) but also 3-fluoroanisole (3) as side product (0.6%) (Table 1, entry 2). We have previously observed that the reaction is moderately sensitive to moisture<sup>9b</sup> on radiochemical scale so we

‡ We found no benefit of adding triphenylphosphane as previously reported,<sup>9b</sup> we argue that the reason is that the iodonium ylide is slowly reduced by the phosphane, and consumed reagent is a problem in preparative chemistry that is not encountered in radiochemistry where substrate is used in >1000 fold excess. <sup>31</sup>P NMR show PPh<sub>3</sub>O as minor side product, ESI.†

Scheme 1 Illustrate a back-translational approach, developing an organic chemistry protocol for synthesising reference compound on preparative scale.

synthesised the anhydrous  $\text{TBAF}(t\text{-BuOH})_4$  complex,<sup>11</sup> which although it increased the yield fourfold (Table 1, entry 2) also produced more of the undesired constitutional isomer that would render purification considerably more difficult (Table 1 entry 3). Heating the reaction mixture for a longer time made no difference (Table 1, entry 4) meaning that the constitutional isomer formation is unrelated to product degradation, varying the temperature did not resolve the selectivity problem either (ESI<sup>†</sup>). Earlier literature reports suggest that fluorination of aryl bromides goes through an aryne intermediate when using the very basic tetraalkylammonium fluorides<sup>12</sup> in DMSO as well as radiofluorination of iodonium ylides using  $\text{KF}/\text{crypt-222}$  in MeCN.<sup>9a</sup> We assumed that since reagent basicity is solvent dependent choosing another solvent could circumvent the problem. However, we found that use of either propylene carbonate or DMSO (Table 1, entries 5 and 6) yielded a comparable ratio of 2-fluoroanisole (2) to 3-fluoroanisole (3) (11 + 1% and 5 + 1% respectively) and that the reaction in both chlorobenzene and MeCN (Table 1, entries 7 and 8) proceeded primarily through an aryne intermediate (12% + 25% and 5 +

Scheme 2 Shows two competing reaction pathways for fluorination of 1 using  $\text{TBAF}(t\text{-BuOH})_4$ . (a) Nucleophilic substitution, (b) TBAF mediated aryne formation and subsequent fluorination yielding both 2 and 3.

9% respectively). We concluded that we have two competing reaction pathways and that the aryne intermediate formation is facilitated by TBAF (Scheme 2). By reducing the equivalents of  $\text{TBAF}(t\text{-BuOH})_4$  from 2 to 1 the yield was marginally decreased to 30% but the formation of 3-fluoroanisole (3) reduced by three quarters to  $0.3 \pm 0.1\%$  (Table 1, entry 9). This finding suggest that use of tetraalkylammonium fluorides in radiofluorination reactions does not suffer from formation of constitutional isomers since only trace quantities of fluoride is used, which is in agreement with Rotstein *et al.*<sup>9c</sup> By increasing the equivalents of  $\text{TBAF}(t\text{-BuOH})_4$  complex to 4 equivalents, 5% desired 2-fluoroanisole (2) and 6% undesired 3-fluoroanisole (3) (Table 1 entry 10) were obtained, further supporting our hypothesis.

With this finding, we decided to move away from tetraalkylammonium fluorides and investigate metal fluorides in combination with phase transfer catalysts (Table 2) to enhance both solubility and nucleophilicity.

Addition of conventional phase transfer catalyst potassium complexing crown ether 18-crown-6 to KF produced only traces of product (Table 2, entry 1). Surprisingly neither CsF nor KF in combination with cryptand crypt-222 produced satisfactory results,  $1 \pm 1\%$  and  $8 \pm 2\%$  of 2-fluoroanisole (2) respectively (Table 2, entries 2 and 3) but with a  $^{19}\text{F}$  NMR spectrum devoid of the 3-fluoroanisole signal (3). We hypothesised that the limited solubility of potassium fluoride<sup>13</sup> in DMF made formation of  $\text{KF}/\text{crypt-222}$  complex too slow to allow for an efficient fluorination reaction since the iodonium ylide substrate slowly degrade under the fluorination conditions.<sup>9b</sup>  $^{13}\text{C}$ -NMR shows only partial formation of  $\text{crypt-222}/\text{K}^+$  complex after 2 hours of heating KF and crypt-222 in DMF at  $130^\circ\text{C}$  (ESI<sup>†</sup>) strengthening our hypothesis. Adding water to the reaction mixture to facilitate  $\text{KF}/\text{crypt-222}$  complex formation would destroy the substrate and strongly diminish the nucleophilicity of fluoride. Therefore, we anticipated that the fluorination complex need to be formed in advance. We made the  $\text{KF}/\text{crypt-222}$  complex from a solution of MeCN/ $\text{H}_2\text{O}$  adding 33 mol%  $\text{K}_2\text{CO}_3$  to hinder evaporation of HF. The complex was thoroughly dried for several days under high vacuum. In line with our hypothesis, the pre-formed  $\text{KF}/\text{crypt-222}$  complex produced a significantly

<sup>a</sup> <sup>19</sup>F NMR yield using 4-fluorobiphenyl as internal standard. Where standard deviation is given, the reaction was performed in duplicate. Product identities were confirmed from spiking with reference compound. <sup>b</sup> Preformed KF/crypt-222 complex containing 33 mol% K<sub>2</sub>CO<sub>3</sub> to avoid formation of HF during drying of KF/crypt-222 complex. Crypt-222 = 4,7,13,16,21,24-hexaoxa-1,10-diazabicyclo[8.8.8]hexacosane.

higher yield (46  $\pm$  2%) gratefully without formation of any constitutional isomers (Table 2, entry 4). The pre-made KF/crypt-222 complex is not visibly hygroscopic and is an easy to weigh free flowing powder (ESI<sup>+</sup>) that can be stored for at least several weeks in a closed vial at room temperature without any impairment of the fluorination yield. Increasing or reducing the equivalents of KF/crypt-222 complex did not improve the yield further (Table 2, entries 5 and 6). The complex readily dissolves in DMF and <sup>13</sup>C-NMR gives three new signals upfield of the host crypt-222.

With the optimised fluorination conditions in hand, we set out to screen a range of substrates to examine the reaction scope (Fig. 1). 4-Fluoroanisole (**4**) was produced in a significantly lower yield (10  $\pm$  1%) than 2-fluoroanisole (**2**, 46  $\pm$  2%), the large difference is likely due to the substrate being both deactivated and lacking an *ortho*-substituent thus not benefitting from the *ortho*-effect.<sup>14</sup> Fluorination of non-activated substrates produced fluorobenzene (**5**) and 4-chloro-1-fluorobenzene (**6**) in modest yields (33  $\pm$  2% and 26  $\pm$  4%) but good enough to be useful for synthesising sufficient material of reference compounds where milligram quantities is sufficient. Fluorination constructing 5-fluoro-*m*-xylene (**7**) proceeded in an acceptable yield (36  $\pm$  1%) whereas sterically hindered constitutional isomer 2-fluoro-*m*-xylene (**8**) was produced in a high yield (78  $\pm$  7%) demonstrating the benefit of *ortho*-substitution. Activated substrates 4-fluorodimethylbenzamide (**9**) and 4-fluorobenzonitrile (**10**) were as expected obtained in high to excellent yields (70  $\pm$  3% and 52  $\pm$  18%) albeit under milder conditions then used for S<sub>N</sub>Ar-fluorinations. Activated drug compound tropane (**11**) was produced in near quantitative yield (88  $\pm$  7%) (90% isolated yield) and the challenging to access morphine (**12**) fluorinated well in 30  $\pm$  1% (20% isolated yield), sufficient for testing its potential use as an NMDA-PET radioligand. The radiotracer [<sup>18</sup>F] **12** was synthesised in 38% isolated yield (150 MBq > 95% RCP after cartridge purification). Activated tropane was readily fluorinated in room temperature yielding 33% of **11**. Encouraged by the positive results we decided to investigate how well the pre-dried KF/crypt-222

**Fig. 1** Fluorination substrate scope under the developed conditions. <sup>19</sup>F NMR yields using 4-fluorobiphenyl as internal standard. Where standard deviation is given, the reaction was performed in duplicate. Product identities were confirmed from spiking with reference compound. Reaction performed on ylide (5  $\mu$ mol) and crypt-222/KF/K<sub>2</sub>CO<sub>3</sub> (4 : 3 : 1) (6.6 mg, 10  $\mu$ mol of KF) in DMF (0.5 ml) at 130 °C for 20 min. Radiofluorination performed using ylide (3.7  $\mu$ mol), crypt-222 (5 mg, 13  $\mu$ mol) K<sub>2</sub>CO<sub>3</sub> (0.92 mg, 5.5  $\mu$ mol) and <sup>18</sup>F<sup>-</sup> (400 MBq) in DMF (0.5 ml) at 130 °C for 20 min. <sup>a</sup>Isolated yield using tracer principle after cartridge purification (C<sub>18</sub> and Si). <sup>b</sup>Non-decay corrected isolated yield after cartridge purification (C<sub>18</sub> and Si) in >95% RCP. RCY = radiochemical yield. Crypt-222 = 4,7,13,16,21,24-hexaoxa-1,10-diazabicyclo[8.8.8]hexacosane. Entry for **2** is identical to Table 2 entry 4.

complex fluorinated activated nitro arenes. We synthesised the NO<sub>2</sub>-precursor of (**11**) for a direct comparison and attempted fluorination under standard conditions obtaining **11** in 34% yield compared to 88  $\pm$  7% when using the iodonium ylide precursor. Fluorination at room temperature produced only traces of product after 1 hour (ESI<sup>+</sup>).

A transition metal free fluorination method based on an anhydrous fluorine complex and iodonium ylides useful for preparative aromatic fluorination reactions is successfully demonstrated. Merging radiochemistry and conventional organic chemistry by employing the same precursor eliminates the need of additional synthetic work. An additional advantage of using a transition metal free methodology is to avoid possible interference during biological characterisation and during

translation into clinical radiochemistry. We successfully demonstrate the use of the methodology by synthesising complex derivatives *via* a late stage fluorination reaction and the radioactive counterparts from the same precursor. The method is a good compliment to existing methodologies and with high yield reproducibility expands the accessible chemical space of fluorinated drug molecules.
