Formation of Mn–Cr mixed oxide nanosheets with enhanced lithium storage properties†

 Liewu Li,  ^a Liping Wang, ^{ab} Mingyu Zhang^{*a} and Qizhong Huang^a

Novel carbon-free $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets are synthesized through thermal decomposition of the facilely co-precipitated Mn–Cr binary hydroxide and a carbonate hybrid precursor. As an anode for lithium-ion batteries, the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode delivers a wonderful electrochemical performance, *i.e.*, an enhanced stability of 913 mA h g^{-1} at a current density of 1 A g^{-1} after 300 cycles, and an excellent rate performance. The excellent electrochemical performance of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode can be ascribed to the interconnected nanosheets and porous structure, as well as the possible synergistic effects between Mn and Cr mixed oxides.

1. Introduction

With the economic growth and the demands of climate protection, rechargeable lithium-ion batteries (LIBs) have established themselves in dominant roles for portable electronic devices and electric vehicles.^{1–4} However, conventional anode materials of graphite cannot meet the urgent demands for heavy-duty applications due to the low theoretical capacity, poor rate performance and serious safety issues owing to the formation of lithium dendrites on its surface even at a charging current density of 4 mA cm^{-2} .^{5,6} In order to meet the requirements for large-scale energy storage, transition metal oxides (TMOs, M = Mn, Fe, Co, Ni, Cu, Cr, *etc.*), especially those of mixed valence oxides involving different metal elements, have been extensively exploited as very promising alternatives to graphite as anode materials (TMOs have about twice the capacity of carbon per unit mass, and three times its density, therefore, TMOs have about 6 times the capacity of carbon per unit volume).^{7–10} Although TMO anode materials exhibit high theoretical capacity for LIBs, they are seriously hampered by the gigantic volume changes and dramatic mechanical stress upon lithiation and delithiation, resulting in cracking and pulverization and loss of electrical contact between particles and the current collector, thereby leading to rapid capacity fading.^{11,12} In order to solve these issues, introducing a second phase element or multiphase materials has proved to be an effective way for the transition metal to increase the electronic conductivity, improve Li^+ diffusivity, separate the multiphase phases from each other,

buffer volume change, as well as accommodate structural stress generated during cycling.^{13–28}

So far many relevant studies have been reported about multiphase TMOs nanocomposite anodes with excellent electrochemical performance.^{29–33} Liu *et al.* showed that by substituting a small amount of Cu into a Co_3O_4 lattice uniformly, the resulting composite electrode material ($\text{Cu}_{3/7}\text{Co}_{18/7}\text{O}_4$) can endure large volume change caused by lithiation/delithiation cycles, thereby maintaining high capacity and cycling stability.³⁴ Lin *et al.* found that $\text{Cr}_2\text{O}_3@\text{Ag}_2\text{O}$ composite showed much higher specific capacity and better cycling stability than those of bare Cr_2O_3 as anode material for LIBs.³⁵ Zhou *et al.* fabricated $\text{CoMn}_2\text{O}_4@\text{TiO}_2$ submicrospheres for advanced LIBs, after 500 cycles at a current density of 1 A g^{-1} , the $\text{CoMn}_2\text{O}_4@\text{TiO}_2$ spheres possessed a high reversible capacity of 940 mA h g^{-1} .³⁶ Despite these achievements in research of multiphase TMOs nanocomposite anodes, the preparation methods are laborious and the cost is not suitable for mass production. Thus, excellent rate capability, outstanding stability and affordable TMOs anode materials produced by scalable synthesis approach should be developed urgently.⁴

Among the TMOs, manganese oxides (MnO_x) have proved to be attractive choices because of their high theoretical capacity, low potential, high abundance and environmental benignity.^{12,37–43} Cr_2O_3 also has been considered as a promising anode material for its high theoretical capacity of 1058 mA h g^{-1} and relatively low lithium insertion potential among metal oxides and low-cost.^{11,44–47} MnCr_2O_4 is an important member of the spinel family and has the normal spinel structure (space group $Fd\bar{3}m$).^{48,49} The MnCr_2O_4 spinel has been widely investigated due to its excellent magnetic and electric properties.⁵⁰ However, to the best of our knowledge, MnCr_2O_4 has not been reported as the anode material for LIBs. Thus, the development of a facile method to synthesize nanostructure MnCr_2O_4 and its

† Electronic supplementary information (ESI) available. See DOI: 10.1039/c8ra04868a

composites and elucidation of their electrochemical reaction mechanism for LIBs is of great importance and necessity.

Herein, we report as first time a co-precipitation method for large-scalable fabrication of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets based on the recent investigations. The facile synthesis approach has the features of scalable capability, environmentally friendly and low cost. As an anode for LIBs, the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode delivers an excellent rate performance and an enhanced reversible capacity of 913 mA h g^{-1} at a current density of 1 A g^{-1} after 300 cycles. Those outstanding electrochemical performances can be ascribed to the unique boundaries between MnCr_2O_4 and Mn_2O_3 , which can promote Li^+ diffusion through the electrode. Furthermore, the structure of interconnected nanosheets and pores can improve electron conductivity in the continuous paths and ensure the electrode full contact with the electrolyte to possess abundant mass-transportation channels, moreover, accommodate a large volume change during charge and discharge processes. Improved rate capacity and cycling stability open the door to design of high-performance LIBs anodes.

2. Experimental section

Preparation of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets

First, $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$ (40 mmol) and $\text{CrCl}_3 \cdot 6\text{H}_2\text{O}$ (20 mmol) were dissolved in 100 mL of deionized water (solution 1), NaOH (140 mmol) and Na_2CO_3 (56 mmol) were also dissolved in 100 mL of deionized water (solution 2). Then solution 2 was dropwise added into solution 1, stirring at the same time. The obtained suspension was maintained at 80°C for 48 h in an oven with sufficient ageing. Next, the precipitate was washed by centrifugal washing and dried at 80°C for 12 h. Finally, the as-dried precursor was heated in air at 5°C min^{-1} up to 800°C , kept at this temperature for 2 h, and cooled naturally to room temperature. Grounded by agate mortar to obtain very fine composite powder (≈ 100 mesh), the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets was synthesized. The same procedures were applied to synthesize the Mn_2O_3 and Cr_2O_3 nanomaterials.

Materials characterization

The morphology and crystal structure of the samples were characterized by scanning electron microscopy (SEM, FEI Nova Nano SEM230), energy dispersive X-ray spectroscopy (EDX, FEI Nova Nano SEM230), transmission electron microscopy (TEM, JEOL JEM-2010), and X-ray diffraction (XRD, Rigaku Dmax/2550 VB + 18 kW). The surface chemical composition of the samples was identified by X-ray photoelectron spectroscopy (XPS) using a multifunctional imaging electron spectrometer (Thermo ESCALAB 250XI) with monochromatic $\text{Al K}\alpha$ radiation. The specific surface areas and pore size distribution of the samples were evaluated from nitrogen adsorption-desorption isotherms using a Quadasorb SI surface characterization analyzer.

Electrochemical testing

The electrodes were prepared by mixing 70 wt% active material, 20 wt% acetylene carbon black and 10 wt% polyvinylidene

fluoride. Then dissolved the mixture in *N*-methyl-2-pyrrolidinone to form slurry. The obtained slurry was coated on copper foil, then dried at 80°C for 12 h under vacuum. Coin cells (CR2032) were fabricated using lithium metal as the counter electrode, Celgard 2400 as the separator, and LiPF_6 (1 M) in ethylene carbonate (EC) and dimethyl carbonate (DMC) with a 1 : 1 volume ratio as the electrolyte. The assembly of the cell was conducted in an Ar-filled glove box with oxygen and moisture contents less than 1 ppm. All measurements were carried out at 25°C . CV measurements were conducted at 0.1 mV s^{-1} within the range of 0.01–3.0 V (vs. Li/Li^+) on a CHI660E electrochemical workstation. Cycle life and rate capability of the cells were tested within a voltage window of 0.01–3.0 V (vs. Li/Li^+) by using a battery testing system (LAND CT2001A, China) at current densities ranging from 0.1 to 3 A g^{-1} . EIS experiments were carried out using a CHI660E electrochemical workstation in the frequency range of 100 kHz to 0.01 Hz.

3. Results and discussion

The $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets was prepared by a facile three-step process involving coprecipitation, lavation and calcination (Fig. 1). First, MnCl_2 and CrCl_3 were dissolved in deionized water to form a transparent solution containing Mn^{2+} and Cr^{3+} . Similarly, NaOH and Na_2CO_3 were dissolved in deionized water to form a mixing transparent solution containing OH^- and CO_3^{2-} . Then, the latter solution was dropwise added into the former solution, stirring at the same time to form a uniform suspension contained $\text{Mn}(\text{OH})_2$, $\text{Cr}(\text{OH})_3$, MnCO_3 and $\text{Cr}_2(\text{CO}_3)_3$. Through post-thermal calcination, the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets was obtained. It worth noting that Mn–Cr binary hydroxides and carbonates hybrid precursor can be uniformly formed efficiently by the facile co-precipitated method. Furthermore, the porous structures were well formed due to the release of CO_2 gas during thermal decomposition of the Mn–Cr binary carbonates.⁴² The details of material synthesis and characterization methods are presented in the experimental section.

From the scanning electron microscopy (SEM) images of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets observed in Fig. 2a and b, there are many nanosheets structures and it interconnected with each other. The interconnected nanosheets structures can not only supply enough space to buffer volume change and accommodate structural stress generated during cycling, but

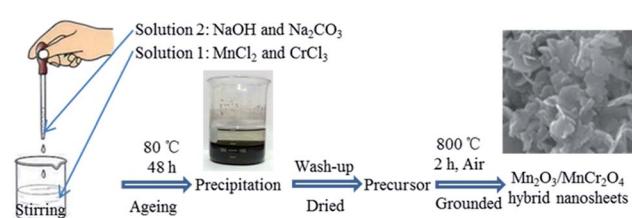

Fig. 1 Schematic illustration of the preparation process of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets.

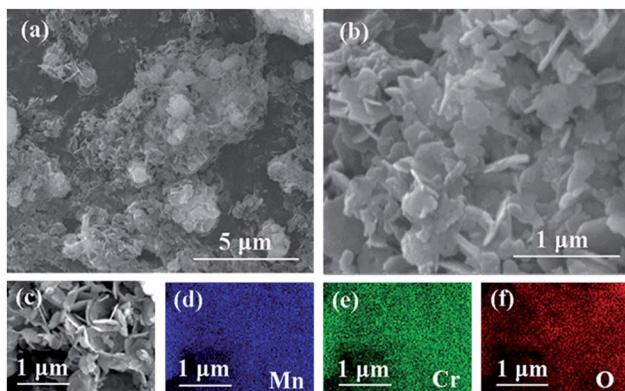

Fig. 2 (a) SEM image of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets; (b) high magnification image of (a); (c)–(f) SEM image and Mn, Cr and O elemental mapping of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets.

also shorten electronic and ionic transport length.^{10,39} The energy dispersive X-ray spectroscopy (EDX) in Fig. 2c–f reveals the existence of Mn, Cr and O verifying the ingredients of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets, and it can be seen that Mn, Cr and O are homogeneously distributed in the entire nanosheets. SEM images of the Mn_2O_3 and Cr_2O_3 nanomaterials are shown in Fig. S1 and S2 (ESI).[†] The atomic contents of Mn and Cr elements in the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets composite were about 43.26% and 20.17%, respectively, which are determined by the EDX (ESI, Fig. S3[†]). The results are in good agreement with the initial ratio of manganese chloride and chromic chloride. Therefore, the ratio of Mn_2O_3 and MnCr_2O_4 in the hybrid nanosheets composite is $\sim 3 : 2$.

The typical XRD pattern of the as-prepared $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets is present in Fig. 3a. Three sharp and intense peaks at around 33.0° , 38.2° and 55.2° are well indexed to the (222), (400) and (440) planes of the cubic Mn_2O_3 phase (JCPDS card no. 41-1442), respectively. Another three sharp and intense peaks at around 30.0° , 35.3° and 61.2° are well indexed to the (220), (311) and (440) planes of the cubic MnCr_2O_4 phase (JCPDS card no. 54-0876). The XRD patterns of the Mn_2O_3 and Cr_2O_3 nanomaterials show in Fig. S4 (ESI).[†] X-ray photoelectron spectroscopy (XPS) was implemented to investigate the elemental composition, chemical states. Feature peaks in the survey spectra corresponding to Mn 2p, Cr 2p and O 1s (Fig. 3b). Corresponding to previous literature, the peaks at 653.2 eV and 641.5 eV in Fig. S5a (ESI)[†] are ascribed to Mn 2p_{1/2} and Mn 2p_{3/2}, and the bonding energies at the Mn 2p_{1/2} and Mn 2p_{3/2} peaks agree well with that of reported for Mn_2O_3 .⁴³ The Mn 2p XPS spectrum exhibited three characteristic peaks at 640.4 eV, 641.8 eV and 643.9 eV, corresponding to spin-orbit peaks of manganese with mixed valence states of +2, +4 and +3, respectively.⁵¹ Similarly, in the Cr 2p XPS spectra, the high-resolution spectra of Cr 2p in Fig. S5b (ESI)[†] shows two distinct peaks at 586.1 eV and 576.7 eV, which are respectively ascribed to Cr 2p_{1/2} and Cr 2p_{3/2} levels, respectively.⁵² The peak fitted at 575.7 eV, 576.8 eV and 578.6 eV mainly belong to Cr²⁺ 2p_{3/2}, Cr⁴⁺ 2p_{3/2} and Cr³⁺ 2p_{3/2} respectively. Consequently, both mixed valence states of +2, +4 and +3 coexisted for manganese and chromium in the as-prepared composites. Brunauer–Emmett–Teller (BET) measurement was carried out to evaluate the specific surface area and pore size distribution of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets (Fig. 3c). A typical IV isotherm with

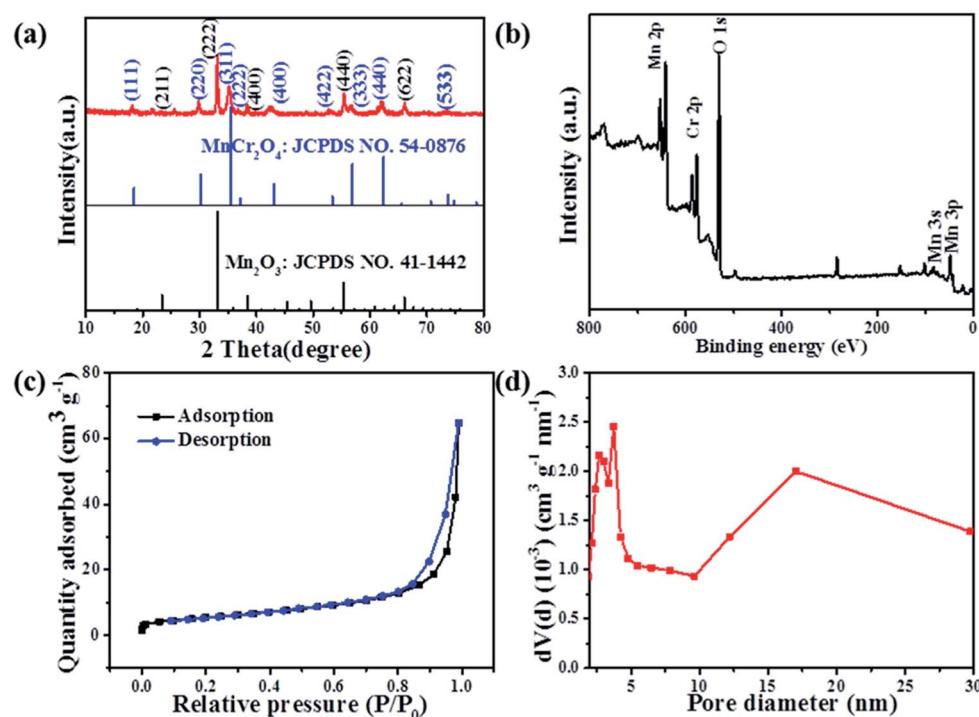

Fig. 3 (a) XRD pattern of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets; (b) XPS survey spectra of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets; (c) BET isotherm plots of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets; (d) BJH pore size distribution of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets.

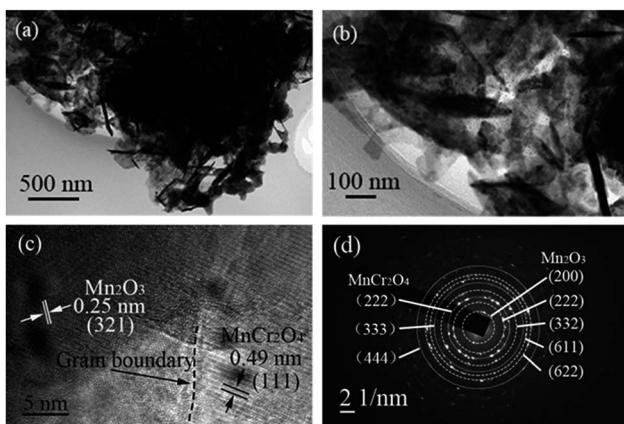

Fig. 4 (a) Bright field TEM image of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets; (b) high-resolution TEM image of (a); (c) high-resolution TEM image of (b); (d) SAED patterns of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets.

a distinct hysteresis loop in the range of 0.8–1.0 P/P_0 can be clearly seen, indicating its mesoporous structures.⁵³ The BET-specific surface area of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets is estimated to be $19.8 \text{ m}^2 \text{ g}^{-1}$. The pore size distribution calculated from the Barrett–Joyner–Halenda (BJH) method, mesopores distribute from 2.68 to 17.01 nm in the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets, and the total pore volume of the nanostructures is calculated to be $0.1 \text{ cm}^3 \text{ g}^{-1}$ (Fig. 3d). High surface area of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets is beneficial to the electrode contact with the electrolyte, moreover, suitable pore size and sufficient pore volume are more favorable for the Li^+ diffusion and alleviating the volumetric expansion during the lithiation and delithiation processes, leading to enhanced cycle performance.⁵⁴

For more accurate information about the morphology and crystal structure, transmission electron microscopy (TEM) was utilized to characterize the interior structure of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets. Fig. 4a clearly illustrates the nanosheets structure, which is in good agreement with the SEM image in Fig. 2b. The nanosheets structure is supposed to accommodate the volume expansion of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ during the lithiation process. It also can be clearly observed from the high-resolution TEM image in Fig. 4b that each nanosheet of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ criss-cross. Fig. 4c reveals the crystalline nature of Mn_2O_3 and MnCr_2O_4 , the observed d -spacing of 0.49 nm corresponds to the (111) plane of cubic MnCr_2O_4 ,⁴⁸ and the observed d -spacing of 0.25 nm corresponds to the (321) plane of cubic Mn_2O_3 . An obvious grain boundary can be observed between the Mn_2O_3 (321) lattice plane and the MnCr_2O_4 (111) lattice plane, indicating that Mn_2O_3 and MnCr_2O_4 strongly bonded with each other, and it is good for preventing the Mn or Cr from aggregation during the lithiation/delithiation processes. Further more, grain boundaries can introduce fast paths for Li^+ diffusion.⁵⁵ Additional crystal structure of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets was analyzed by the selected area electron diffraction (SAED) patterns (Fig. 4d). The SAED patterns confirm that the

nanosheets are Mn_2O_3 and MnCr_2O_4 hybrid phase, which are in good agreement with the XRD results.

The electrochemical performance of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets and other comparison anode materials have been investigated using lithium ion half cells. All of the electrochemical measurements were tested between 0.01 and 3.0 V (vs. Li/Li^+) at 25 °C.

Fig. 5a displays the typical cyclic voltammetry (CV) curves of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode for the initial five cycles at a scan rate of 0.1 mV s⁻¹. In the initial cathodic process, the small peak at about 0.81 V is resulted from the formation of a solid–electrolyte interface (SEI) film.¹² Further more, two main lithiation peaks centered at 0.30 and 0.11 V can be assigned to the conversion reaction of the Mn_2O_3 and MnCr_2O_4 with lithium.^{11,12} For the second and following cycles, the peaks located at 0.81 V and 0.11 V disappeared, and the reduction peak shifted to higher potential of 0.44 V due to the improved reaction kinetics after the first lithiation.³⁷ During the anodic process, the oxidation peak located at 1.3 V in the reverse sweep is ascribed to the re-oxidation of metallic Mn/MnO , $\text{Cr}/\text{Cr}_2\text{O}_3$ and the decomposition of Li_2O .^{11,12} The charge–discharge profiles at the current densities of 0.1, 0.2, 0.5, 1, 2 and 3 A g⁻¹ for the 1st, 11th, 16th, 21st, 31st and 36th cycles are displayed in Fig. 5b. The potential of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode increases/decreases monotonically with obvious potential plateau when charge/discharge at various current density, which is a typical behavior of ion conversion dominated energy storage mechanism.⁹ The distinct plateaus at around 0.5 V and 1.3 V in the discharge and charge profiles are in accordance with the CV curves, matching well with the reduction and oxidation of Mn^{3+} and Mn, respectively. The distinct plateaus at around 0.2 V and 0.15 V in the discharge profile can be related to the reduction of Mn^{2+} to the $\text{Li}_2\text{O}/\text{Mn}$ and Cr^{3+} to the $\text{Li}_2\text{O}/\text{Cr}$.^{56,57} The first discharge and charge capacities are 1207 mA h g⁻¹ and 880 mA h g⁻¹, respectively. The ~27% irreversible capacity loss for the first cycle can be ascribed to the formation of the SEI layer and the decomposition of the electrolyte.³⁷ The electrochemical reactions during cycling can be concluded as follows:

It is worth pointing out that the reversed conversion (oxidation) potential of metal Mn to MnO (1.3 V) during Li^+ extraction process is higher than the conversion oxidation potential of metal Cr to Cr_2O_3 (1.27 V).^{56,58} In other words, the formed well-dispersed Mn nanoparticles in $\text{Cr}/\text{Li}_2\text{O}$ matrices after full lithiation of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ can work as anchors to effectively prohibit the diffusion and coarsening of Cr nanocrystals during the reversed conversion reactions of Cr, giving rise to the obviously enhanced cycling efficiency and stability.

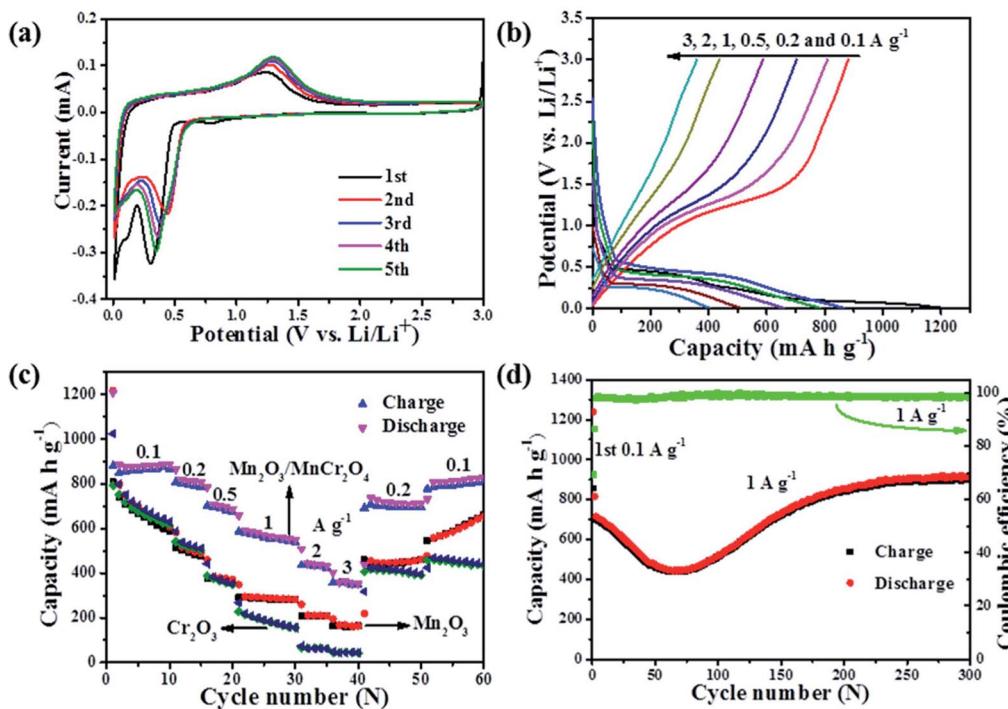

Fig. 5 (a) Cyclic voltammograms of the Mn₂O₃/MnCr₂O₄ electrode at a scan rate of 0.1 mV s⁻¹ with the potential ranging from 0.01 to 3 V for the initial five cycles; (b) discharge and charge profiles at the current densities ranging from 0.1 to 3 A g⁻¹ for the Mn₂O₃/MnCr₂O₄ electrode; (c) rate performance of the Mn₂O₃, Mn₂O₃/MnCr₂O₄ and Cr₂O₃ electrode at different current densities; (d) cycling performance and coulombic efficiency of the Mn₂O₃/MnCr₂O₄ electrode at 1 A g⁻¹.

The upgrade of electrochemical properties is also reflected in rate performances, and the comparison between the Mn₂O₃, Mn₂O₃/MnCr₂O₄ and Cr₂O₃ electrodes were evaluated in the range from 0.1 to 3 A g⁻¹ (Fig. 5c). For the Mn₂O₃/MnCr₂O₄ electrode, the average reversible discharge capacities of ~861, 734, 712, 577, 451 and 366 mA h g⁻¹ are obtained at 0.1, 0.2, 0.5, 1, 2 and 3 A g⁻¹, respectively. Obviously, the capacity gradually falls off as the current density increases but still remains relatively high. When the current density is reduced back to 0.2 A g⁻¹, the charge capacity also recovers to 693 mA h g⁻¹, indicating the high stability as well as excellent reversibility of the electrode. The rate performance of the Mn₂O₃/MnCr₂O₄ electrode is obviously much better than those of Mn₂O₃ and Cr₂O₃ electrodes. The excellent rate capability may be benefited from the presence of the interconnected nanosheets and porous structure, as well as the grain boundaries for elevating the transportation of both Li⁺ and electrons.¹⁰

To understand the capacity and stability of the Mn₂O₃, Mn₂O₃/MnCr₂O₄ and Cr₂O₃ electrodes, the cycling stability test was carried out at a current density of 1 A g⁻¹ for 200 cycles (ESI, Fig. S6†). The initial Coulombic efficiency of the Mn₂O₃, Mn₂O₃/MnCr₂O₄ and Cr₂O₃ electrodes are 55.4%, 72.9% and 79.2%, respectively. In the first cycle, a large irreversible capacity can be observed because of the formation of the SEI composite.³⁷ The discharge capacities of the Mn₂O₃, Mn₂O₃/MnCr₂O₄ and Cr₂O₃ electrodes are 400, 854 and 113 mA h g⁻¹ in the 200th cycle, respectively. The discharge capacity retention rate of the Mn₂O₃, Mn₂O₃/MnCr₂O₄ and Cr₂O₃ electrodes are 74.5%, 104.8% and

38.3% compared with the 2nd cycle, respectively. The discharge capacity of the Mn₂O₃ decreases to 242 mA h g⁻¹ in the 66th cycle, then increases to 429 mA h g⁻¹ in the 157th cycle, after that, the capacity decreases slowly. The discharge capacity of the Mn₂O₃/MnCr₂O₄ electrode shows an obvious capacity fading to 442 mA h g⁻¹ in the 64th cycle, then increases continuously to 854 mA h g⁻¹ in the 200th cycle. The discharge capacity of the Cr₂O₃ electrode falls down rapidly to 164 mA h g⁻¹ in the 10th cycle, then decreases slowly. The phenomenon may be ascribed to the comprehensive effects of the continuous formation of the SEI film on the new active surfaces caused by the repetitive volume change during the discharge/charge cycles.⁵⁹ The lithiation induced reactivation of the Mn₂O₃ and Mn₂O₃/MnCr₂O₄ electrodes is a similar phenomenon observed in transition metal oxide electrodes.^{7,8} The excellent stability of the Mn₂O₃/MnCr₂O₄ electrode also can be ascribed to the special structure of the nanosheets and porous structure, which can effectively buffer volume expansion and prevent the aggregation during the conversion processes of the formation and decomposition of Li₂O, accompanying the reduction and oxidation of metal nanoparticles.^{10,11,44}

The cycling performances of the Mn₂O₃/MnCr₂O₄ electrode at the current densities of 0.1, 0.5 and 1 A g⁻¹ show in Fig. 5d and Fig. S7 (ESI).[†] Under different current densities, the discharge capacities show the same tendency, gradually decreases first, then increases, it obtains 913 mA h g⁻¹ at 1 A g⁻¹ in the 300th cycle, more than 200% capacity recovery from the lowest value at the same rate. The drastic capacity fading is

caused by the lithiation-induced mechanical degradation and the formation of unstable SEI.⁶⁰ The gradually increasing capacity can be reasonably explained by the electrochemical activation of active materials and electrochemical catalysis of Li_2O and metal grains, which is a common phenomenon observed in other TMOs.⁶¹ The coulombic efficiency increases to 98% after three initial cycles, and then remains over this level until 400 cycles are completed. High coulombic efficiency indicates that a stable SEI layer formed during the initial cycles. With the formation of a stable SEI layer, the structure-refined electrode exhibits a higher reversible specific capacity. The $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode also exhibits a long cycling performance at a high current density of 3 A g^{-1} for 1000 cycles (ESI, Fig. S8†). The discharge capacity gradually decreases to 208 mA h g^{-1} in the 159th cycle, then increases to 380 mA h g^{-1} in the 322th cycle, and it still obtains 320 mA h g^{-1} in the 1000th cycle.

To further reveal the differences of transport kinetics, the electrochemical impedance spectra (EIS) of all materials were analyzed. Fig. 6 displays the Nyquist plots of the Mn_2O_3 , $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ and Cr_2O_3 electrodes. As observed in the Nyquist plots, all the three samples show a compressed semicircle in the high frequency region and an inclined line in the low-frequency region, which can be assigned to the charge-transfer resistance and semidiffusion of Li^+ respectively.¹⁸ It can be clearly observed that the Mn_2O_3 nanocomposite electrode shows the lowest charge transfer resistance, and $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode has a significantly lower charge transfer resistance than the Cr_2O_3 electrode, suggesting that increase the content of Mn_2O_3 can improve the electrical conductivity of $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode. So the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode obtained more transport channels for electrons and Li^+ . Herein, not only can be the particular structure of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ nanosheets mitigates the aggregation and contact resistance, but it also can provide a short way for electrons and ions to transfer, which is in favor of its outstanding electrochemical performance.

Surface SEM images of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode at 0th and 1000th cycles were measured to confirm the influence of nanosheets structure on the integrity of electrodes after cycling (Fig. 7). Surface of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode before cycling has uniform mixed active materials and conductive agents with

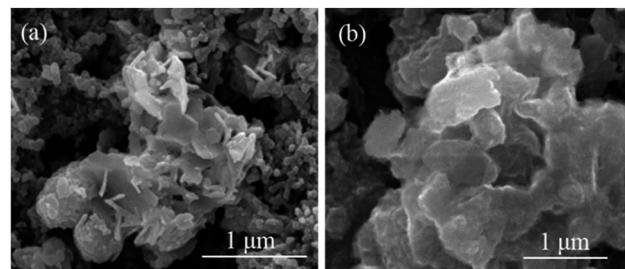

Fig. 7 SEM images of the electrode for the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ before (a) and after (b) 1000 cycles at 1 A g^{-1} .

integrated structure (Fig. 7a). After 1000 cycles at 3 A g^{-1} , the electrode retains its integrated shape as shows in Fig. 7b, indicating the good structural stability of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ during the process of Li^+ uptake/extraction. The nanosheets structure mitigates the volume changes and thus facilitates electrode stability and good electrical contact during long cycling.⁴⁴

Based on the above experimental results and analysis, we can infer that the following strategically interdependent characteristics of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets are responsible for the outstanding LIBs performance. The nanosheets structure can effectively withstand the mechanical stress during the charge-discharge processes. Further more, the interconnected nanosheets and porous structure facilitates quick transmission channels for Li^+ and electrons among active materials, and can also protect the stable structure from collapse and aggregation so as to reduce the resistance. Therefore, both the poor conductivity and volume changes of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode can be circumvented by the as-prepared $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets, which is beneficial for directing other multiphase TMOs electrode designs.

4. Conclusions

In conclusion, the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets have been successfully prepared from a facile synthesis approach by thermal decomposition of the Mn–Cr binary hydroxides and carbonate hybrid precursor. The special structure was designed simultaneously to enable the effective restriction of the volumetric expansion of the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ as well as provide good electron and ion transport capability based on electrochemical impedance spectra. The electrochemical measurements demonstrate that the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ electrode delivers an excellent reversible capacity of 913 mA h g^{-1} at a current density of 1 A g^{-1} after 300 cycles and excellent rate performance. The facile and scalable approach to fabricate the $\text{Mn}_2\text{O}_3/\text{MnCr}_2\text{O}_4$ hybrid nanosheets can expand the scope of the design concept of multiphase TMOs for LIBs application.
