# Functionalization of silver nanoparticles with mPEGylated luteolin for selective visual detection of Hg<sup>2+</sup> in water sample†

Weixia Qing,<sup>a</sup> Mengnan Zhao,<sup>b</sup> Conghui Kou,<sup>b</sup> Minghua Lu<sup>id</sup><sup>c</sup> and Yong Wang<sup>id</sup><sup>\*c</sup>

A novel colorimetric sensor based on mPEGylated luteolin-functionalized silver nanoparticles (mPEGylated luteolin-AgNPs) in an aqueous solution was prepared. The mPEGylated luteolin-AgNP solution was utilized to detect Hg<sup>2+</sup> with high sensitivity and selectivity in the presence of other metal cations including Na<sup>+</sup>, K<sup>+</sup>, Mg<sup>2+</sup>, Zn<sup>2+</sup>, Ni<sup>2+</sup>, Mn<sup>2+</sup>, Ba<sup>2+</sup>, Pb<sup>2+</sup>, Sr<sup>2+</sup>, Ca<sup>2+</sup>, Cd<sup>2+</sup>, Al<sup>3+</sup> and Cu<sup>2+</sup>. The solution could be induced to aggregate, and a color change from yellow-brown to colorless was observed in the presence of Hg<sup>2+</sup>. Meanwhile, the sensor was successfully used to detect Hg<sup>2+</sup> in tap water with satisfactory recovery ranges using the standard addition method.

## 1. Introduction

As is widely known, Hg<sup>2+</sup> is one of the most dangerous heavy metal pollutants in the environment because it can harm our brain, kidneys, and nervous and endocrine systems.<sup>1–3</sup> Therefore, the development of effective methods to monitor Hg<sup>2+</sup> in aqueous solutions is crucial. Generally, Hg<sup>2+</sup> is determined using common analytical methods including inductively coupled plasma mass spectrometry,<sup>4</sup> atomic absorption/emission spectroscopy,<sup>5</sup> and atomic fluorescence spectrometry.<sup>6</sup> However, these techniques are costly, time-consuming and complicated in terms of the sample preparation processes. Thus, developing a simple and sensitive method is currently a challenge. Metal nanoparticles, especially silver nanoparticles (AgNPs), have been of high interest in the sensor field because of their excellent optical properties.<sup>7,8</sup> Until now, AgNPs have been widely used for the detection of Hg<sup>2+</sup>.<sup>9–12</sup> It is known that colorimetric sensing based on the naked eye response cannot be replaced by other methods because of its online monitoring without the need of any sophisticated instruments. Recently, colorimetric sensors based on functionalized AgNPs have also attracted the attention of researchers.<sup>13–16</sup>

In our previous study, a facile route for the green synthesis of mPEGylated luteolin-capped silver nanoparticles (mPEGylated luteolin-AgNPs) was reported.<sup>17</sup> This study mainly focused on the preparative and antimicrobial aspects of the system. Herein, mPEGylated luteolin-AgNPs were considered as a colorimetric

sensor for the detection of Hg<sup>2+</sup> in aqueous solutions. The mPEGylated luteolin-AgNP sensor was found to be highly sensitive and selective towards Hg<sup>2+</sup> without any interference from other metal cations. Finally, the sensor was successfully used to detect Hg<sup>2+</sup> in a tap water sample with satisfactory recovery ranges. The sensor exhibited high potential for practical applications due to its selective monitoring of Hg<sup>2+</sup> in aqueous solutions.

## 2. Experimental

### 2.1. Materials and instrumentation

Silver nitrate (AgNO<sub>3</sub>), luteolin and mPEG (MW = 1900) were purchased from Sigma-Aldrich. Benzyl bromide, 4-toluene sulfonylchloride, cesium carbonate and anhydrous dimethyl formamide were purchased from J&K Chemical Technology (Beijing China). All the different cations including NaNO<sub>3</sub>, KNO<sub>3</sub>, Pb(NO<sub>3</sub>)<sub>2</sub>, Sr(NO<sub>3</sub>)<sub>2</sub>, Mg(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O, Zn(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O, Ni(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O, Ca(NO<sub>3</sub>)<sub>2</sub>·4H<sub>2</sub>O, Al(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O, Cd(NO<sub>3</sub>)<sub>2</sub>·4H<sub>2</sub>O, Mn(NO<sub>3</sub>)<sub>2</sub>·4H<sub>2</sub>O, Cu(NO<sub>3</sub>)<sub>2</sub>·3H<sub>2</sub>O, HgSO<sub>4</sub> and BaCl<sub>2</sub>·2H<sub>2</sub>O were of analytical grade and were used without further purification; they were supplied by Sinopharm Chemical Reagent Co. Ltd (Shanghai, China). UV-Vis spectroscopic studies were carried out on a TU-1900 spectrophotometer (Beijing Purkinje General Instrument Co. Ltd.) with 1 cm quartz cell. The morphologies were studied on JEM-2100 (JEOL Co., Japan). The average size and zeta potential were recorded on Nano ZS 90 at 25 °C. The photographs of mPEGylated luteolin-AgNP solution used for visual colorimetric detection were taken with a digital camera.

### 2.2. Synthesis of the mPEGylated luteolin-AgNPs

As shown in Fig. S1,† the synthetic method of mPEGylated luteolin-AgNPs was in accordance with previously reported

<sup>a</sup>Laboratory for Nanomedicine, School of Basic Medical Science, Henan University, Kaifeng, 475004, P. R. China

<sup>b</sup>Pharmaceutical College, Henan University, Kaifeng, 475004, P. R. China

<sup>c</sup>College of Chemistry and Chemical Engineering, Henan University, Kaifeng, 475004, P. R. China. E-mail: wangyong@henu.edu.cn

methods.<sup>17,18</sup> The freshly prepared mPEGylated luteolin-AgNP solution was stored at 4 °C in a refrigerator.

### 2.3. The colorimetric determination of Hg<sup>2+</sup>

For colorimetric detection of Hg<sup>2+</sup>, the prepared mPEGylated luteolin-AgNPs were diluted with deionized water, and the resulting concentration was calculated to be 10<sup>-4</sup> mol L<sup>-1</sup>. To study the metal ion detection ability of mPEGylated luteolin-AgNPs, 0.1 mL aliquots of representative metal cations (0.01 mol L<sup>-1</sup>) including Na<sup>+</sup>, K<sup>+</sup>, Mg<sup>2+</sup>, Zn<sup>2+</sup>, Ni<sup>2+</sup>, Mn<sup>2+</sup>, Hg<sup>2+</sup>, Ba<sup>2+</sup>, Pb<sup>2+</sup>, Sr<sup>2+</sup>, Ca<sup>2+</sup>, Cd<sup>2+</sup>, Al<sup>3+</sup> and Cu<sup>2+</sup> were added into the prepared mPEGylated luteolin-AgNP solution (2 mL) under similar conditions. After the solution had been mixed for 2 minutes, the changes in UV-Vis absorption spectra were monitored at room temperature. The photographs were also taken with a digital camera.

## 3. Results and discussion

### 3.1. The formation of mPEGylated luteolin-AgNPs

The redox potentials of luteolin and Ag<sup>+</sup> were 0.35 and 0.779 V, respectively, which were easy to achieve by *in situ* synthesis.<sup>19</sup> Here, Ag<sup>+</sup> was easily reduced to Ag<sup>0</sup> by two adjacent hydroxyls of mPEGylated luteolin; at the same time, dihydroxy underwent two-electron oxidation to quinone form. The prepared AgNPs were stabilized through electrostatic interactions and mPEG.

The prepared AgNP solution exhibited a yellow-brown color in aqueous solution, and the maximum absorbance value was detected at 440 nm by recording UV-Vis spectra at different time intervals (Fig. 1a). Fig. 1a shows that the absorbance intensity no longer increased after 30 minutes. The corresponding zeta potential of AgNPs showed a sharp peak at -25.5 mV (Fig. 1b), which indicated that the surface was negatively charged and the solution would be stable for a long period.<sup>20</sup> Meanwhile the FT-

IR spectrum (Fig. S2†) showed that the band at 3423 cm<sup>-1</sup> corresponded to the O-H stretching vibration, and the bands at 1637 and 1738 cm<sup>-1</sup> corresponded to the C=O stretching vibration. The above results proved that the surface of AgNPs was rich in hydroxyl and carbonyl groups.

The pH value was tuned between 2.0 and 10.0 using HCl or NaOH solution (0.01 mol L<sup>-1</sup>); then, the stability of the mPEGylated luteolin-AgNPs was studied. Fig. S3† shows the UV-Vis spectrum of the mPEGylated luteolin-AgNPs at different pH values (2, 4, 6, 7, 8 and 10). The changes in pH did not cause any visual change in the color, and there were some blue shifts in the peak positions at pH 2 and 4, which showed that the mPEGylated luteolin-AgNPs could be used in the pH range of 6–10.

### 3.2. Selective recognition of mPEGylated luteolin-AgNPs towards Hg<sup>2+</sup>

The UV-Vis spectra of mPEGylated luteolin-AgNP solution (2.0 mL) after the addition of fourteen varieties of metal ions in aqueous solution (0.1 mL, 0.01 mol L<sup>-1</sup>) are shown in Fig. 2. The color change from yellow-brown to colorless immediately in the presence of Hg<sup>2+</sup>, as observed in Fig. 2a, corresponded to

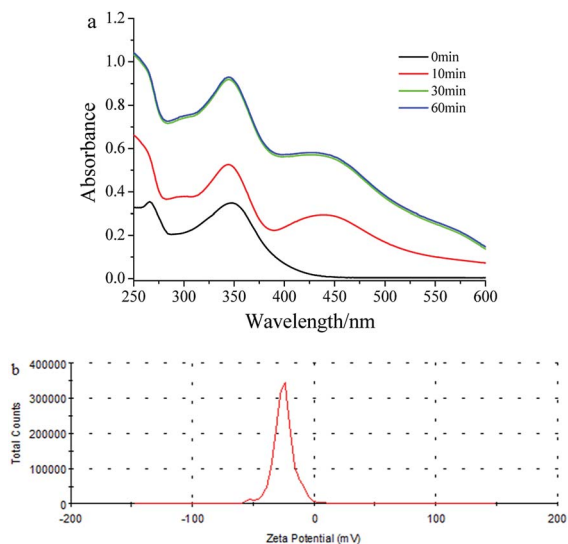

Fig. 1 (a) UV-Vis spectra recorded during the formation of mPEGylated luteolin-AgNP solution at different time intervals. (b) Zeta potential stability measurements for mPEGylated luteolin-AgNPs.

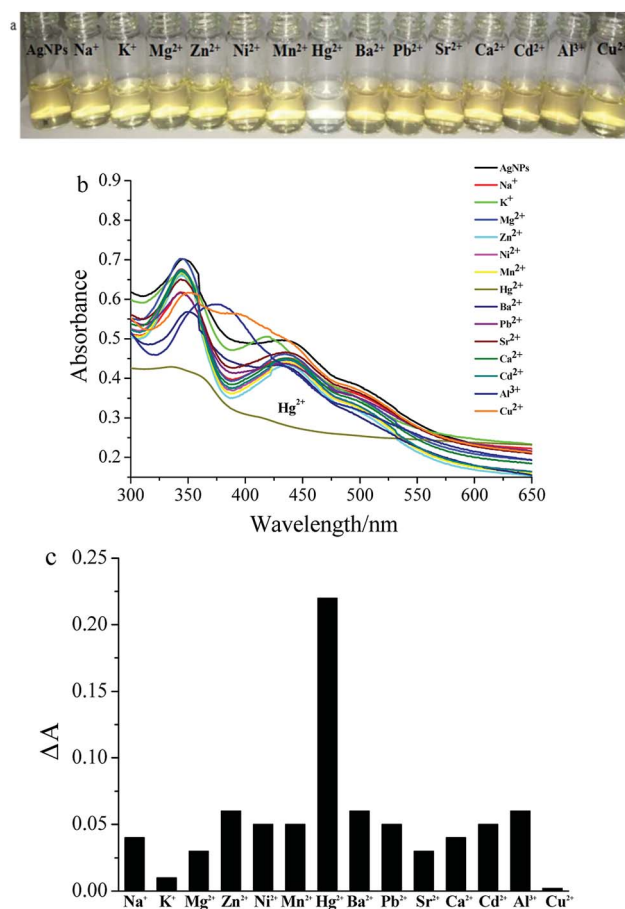

Fig. 2 (a) The photographic images, (b) UV-Vis spectra of mPEGylated luteolin-AgNP solution in the presence of different metal ions; (c) the bar diagram exhibits the magnitude of change  $\Delta A$  for various cations.

disappearance of the absorption peak at 440 nm in Fig. 2b. The colorimetric response of mPEGylated luteolin-AgNPs to various metal ions is shown in Fig. 2c, and a clear increase in the  $\Delta A$  value was observed in the presence of  $\text{Hg}^{2+}$ . Here,  $\Delta A$  is the UV absorption difference value between  $A_0$  and  $A$ .  $A_0$  was measured in the presence of only AgNPs, and  $A$  was measured in the presence of both AgNPs and various metal ions. Furthermore, as shown in Fig. S4,<sup>†</sup> the colorimetric detection ability of  $\text{Hg}^{2+}$  was studied in the presence of equal amounts of  $\text{Hg}^{2+}$  and other metal ions, and there was still no remarkable interference in color. All in all, the other metal ions had no clear effect on either the color or the UV-Vis spectra; thus, it was confirmed that mPEGylated luteolin-AgNPs were effectively selective for  $\text{Hg}^{2+}$ .

### 3.3. Interaction of mPEGylated luteolin-AgNPs with $\text{Hg}^{2+}$

After addition of different concentrations of  $\text{Hg}^{2+}$  to an mPEGylated luteolin-AgNP solution, the solution color became clearer gradually until it turned colorless (Fig. 3a). Related UV-Vis spectra are shown in Fig. 3b, and the results showed that the absorption peak at 440 nm gradually decreased and finally disappeared.

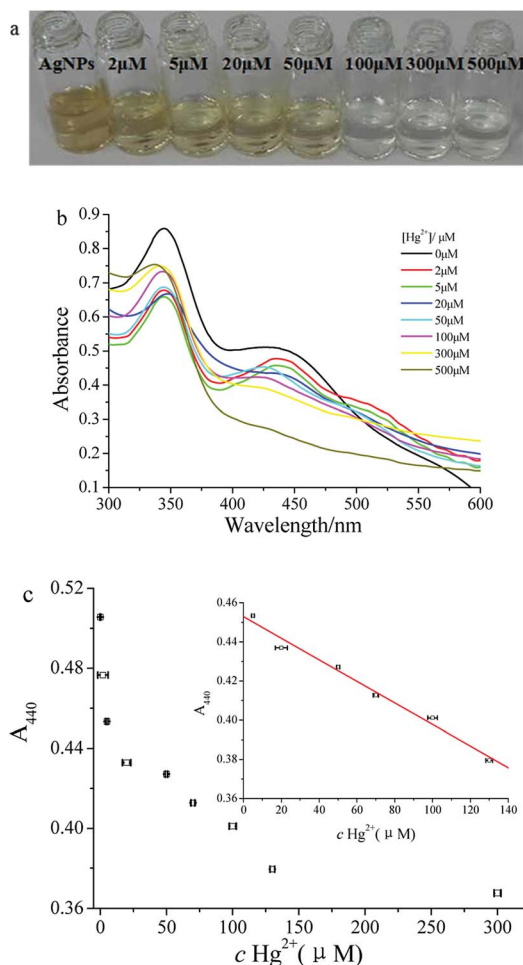

Fig. 3 (a) Images, (b) UV-Vis spectra and (c)  $A_{440}$  of mPEGylated luteolin-AgNP solution with various concentrations of  $\text{Hg}^{2+}$ .

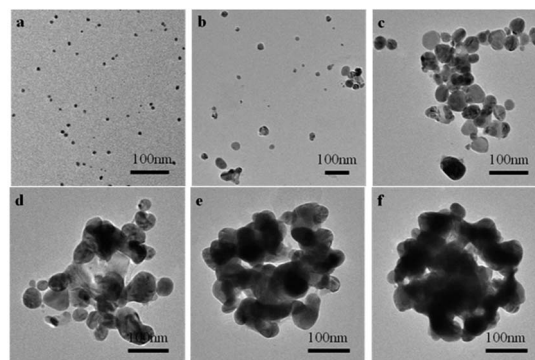

Fig. 4 TEM images of the mPEGylated luteolin-AgNPs with various concentrations of  $\text{Hg}^{2+}$ . (a) 0, (b) 2  $\mu\text{M}$ , (c) 20  $\mu\text{M}$ , (d) 100  $\mu\text{M}$ , (e) 300  $\mu\text{M}$ , (f) 500  $\mu\text{M}$ .

To study the reaction mechanism between mPEGylated luteolin-AgNPs and  $\text{Hg}^{2+}$ , TEM results of the mPEGylated luteolin-AgNPs in the presence of  $\text{Hg}^{2+}$  are shown in Fig. 4. Before the addition of  $\text{Hg}^{2+}$ , mPEGylated luteolin-AgNPs were dispersed uniformly in aqueous solution. After the addition of  $\text{Hg}^{2+}$ , the degree of mPEGylated luteolin-AgNP aggregation increased with the increasing  $\text{Hg}^{2+}$  concentration. As shown in Fig. S5a,<sup>†</sup> when the concentration of  $\text{Hg}^{2+}$  was in the range of 0–500  $\mu\text{M}$ , the average size of mPEGylated luteolin-AgNPs increased from 77 to 170 nm, which was in good agreement with the TEM results.<sup>21</sup> The aggregation phenomenon resulted in changes in not only color but also instability of the mPEGylated luteolin-AgNPs. As shown in Fig. S5b,<sup>†</sup> the absolute value of zeta potential decreased, which proved that the nanoparticles were increasingly unstable.

To further discuss the possible reaction mechanisms, the  $^1\text{H}$ NMR spectra of mPEGylated luteolin-AgNPs in the absence and presence of  $\text{Hg}^{2+}$  were characterized (Fig. S6<sup>†</sup>). From Fig. S6,<sup>†</sup> it can be observed that the proton peaks on the benzene ring have basically disappeared in the presence of  $\text{Hg}^{2+}$ , which showed that the mPEGylated luteolin-AgNPs possessed typical H donor ligand binding to  $\text{Hg}^{2+}$ , and the possible mechanism is shown in Fig. 5. Moreover, an amalgam may be formed in this process.<sup>22</sup>

### 3.4. Application of mPEGylated luteolin-AgNPs in tap water samples

Quantitative analysis of  $\text{Hg}^{2+}$  was studied by UV-Vis spectroscopy, which mainly monitored the color change of the solution. Typically, 0.1 mL aliquots of various concentrations of  $\text{Hg}^{2+}$  were added into 2.0 mL of mPEGylated luteolin-AgNP solution and mixed well for 2 minutes; then,  $A_{440}$  was tested (Fig. 3c). As shown in the inset of Fig. 3c, the calibration curve ( $A = 0.4529 - 5.509 \times 10^{-4} c$ ) was linearly proportional to the concentration of  $\text{Hg}^{2+}$  between 5 and 130  $\mu\text{M}$  with a correlation coefficient of 0.9924. The detection limit for  $\text{Hg}^{2+}$  was 0.97  $\mu\text{M}$ . Compared with some previously reported sensors (Table 1), the present colorimetric sensor showed more sensitivity and a wider linear range.

To verify the feasibility of this method, a tap water sample was chosen for the determination of  $\text{Hg}^{2+}$ . The standard

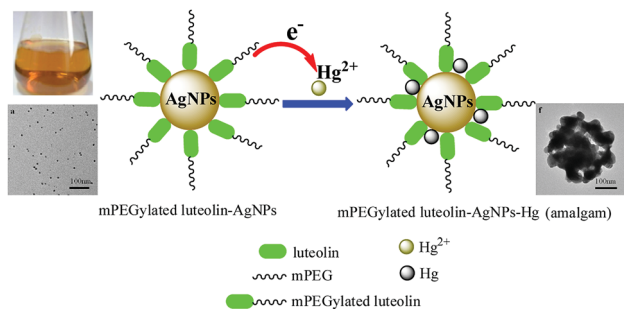

Fig. 5 Possible schematic representation of mPEGylated luteolin-AgNPs for detection of  $\text{Hg}^{2+}$ .

Table 1 Comparison of  $\text{Hg}^{2+}$  determination with previously reported results

Functionalization of AgNPs	Linear range ( $\mu\text{M}$ )	LOD ( $\mu\text{M}$ )	Ref.
mPEG-luteolin	5–130	0.9	This work
Garlic extract	—	2	23
Soap-root extract	10–100	2.2	24

Gln-His	100–1000	25.48	25
Gln-His/NaCl	1–500	0.9	

addition method was employed for the calculation recovery, and the tap water sample was spiked with different known concentrations of  $\text{Hg}^{2+}$ . The detected recovery rates for the prepared sensor ranged from 95.4% to 107.5% with RSD below 2%. These results indicated that our prepared sensor was reliable, feasible and sensitive to detect  $\text{Hg}^{2+}$  in water samples.

## 4. Conclusions

In summary, the mPEGylated luteolin-AgNP solution was first utilized for the detection of  $\text{Hg}^{2+}$ . The  $\text{Hg}^{2+}$  concentration could be directly monitored using the color change of the mPEGylated luteolin-AgNP solution; this sensor is a novel colorimetric sensor for rapid and easy  $\text{Hg}^{2+}$  detection. In this study, the simple detection and good recovery of the proposed method were demonstrated, and it has potential applications in environmental and analytical chemistry fields.
