Fabrication of a Cu/Zn co-incorporated calcium phosphate scaffold-derived GDF-5 sustained release system with enhanced angiogenesis and osteogenesis properties†

Dongqin Xiao,^{‡a} Fei Yang,^{‡a} Qiao Zhao,^b Shixiao Chen,^c Feng Shi,^d Xiacong Xiang,^a Li Deng,^a Xiao Sun,^a Jie Weng^e and Gang Feng^{*ab}

Synthetic scaffolds with multifunctional properties, including angiogenesis and osteogenesis capacities, play an essential role in accelerating bone regeneration. In this study, various concentrations of Cu/Zn ions were incorporated into biphasic calcium phosphate (BCP) scaffolds, and then growth differentiation factor-5 (GDF-5)-loaded poly(lactide-co-glycolide) (PLGA) microspheres were attached onto the ion-doped scaffold. The results demonstrated that with increasing concentration of dopants, the scaffold surface gradually changed from smooth grain crystalline to rough microparticles, and further to a nanoflake film. Additionally, the mass ratio of β -tricalcium phosphate/hydroxyapatite increased with the dopant concentration. Furthermore, GDF-5-loaded PLGA microspheres attached onto the BCP scaffold surface exhibited a sustained release. *In vitro* co-culture of bone mesenchymal stem cells and vascular endothelial cells showed that the addition of Cu/Zn ions and GDF-5 in the BCP scaffold not only accelerated cell proliferation, but also promoted cell differentiation by enhancing the alkaline phosphatase activity and bone-related gene expression. Moreover, the vascular endothelial growth factor secretion level increased with the dopant concentration, and attained a maximum when GDF-5 was added into the ions-doped scaffold. These findings indicated that BCP scaffold co-doped with Cu/Zn ions exhibited a combined effect of both metal ions, including angiogenic and osteogenic capacities. Moreover, GDF-5 addition further enhanced both the angiogenic and osteogenic capacities of the BCP scaffold. The Cu/Zn co-incorporated BCP scaffold-derived GDF-5 sustained release system produced multifunctional scaffolds with improved angiogenesis and osteogenesis properties.

Introduction

Because of the limitations of the current therapies based on the usage of autologous bone grafts, allografts and xenografts, synthetic scaffolds for the repair of segmental bone defects have attracted increasing interest.^{1,2} The ideal synthetic scaffold for

bone tissue repair should promote cell migration, angiogenesis and new bone formation.³ To achieve these requirements, three-dimensional scaffolds were tailored by controlling porous structure, surface topography and chemical composition to enhance their osteoinduction properties for better healing effects.^{4–7} However, poor angiogenesis within synthetic scaffolds has been recognized as the main hurdle limiting the clinical application of bone tissue-engineering scaffolds. Implant failure and osteonecrosis occurred when there was a lack of inner vascular network to supply nutrients and oxygen to cells within the tissue.^{8,9} Therefore, numerous efforts have been devoted to stimulate or facilitate angiogenesis or vascularization in bone tissue-engineering scaffolds as well as osteogenesis, including the delivery of vascular endothelial growth factor (VEGF) or bone morphogenetic protein-2 (BMP-2) released from polymer or ceramic scaffolds.^{10,11} Although desirable results have been obtained during BMP-2 and VEGF applications in bone tissue repair, it is noteworthy that serious side effects, including ectopic and unwanted vascularization and bone formation, have become increasingly resistant to

approving the usage of such proteins.^{12–14} Therefore, alternative safer growth factors or potential strategies should be explored to enhance the osteogenesis and angiogenesis capacities of bone tissue-engineering scaffolds.

Growth differentiation factor-5 (GDF-5), as a member of the BMP family, is best known for its role in early limb development and long-bone fracture healing. However, GDF-5 has been studied less in bone tissue regeneration compared with BMP-2, which may be associated with its origin from cartilage tissue. Previous studies have found that GDF-5 promoted the recruitment of mesenchymal stem cells (MSCs) and their differentiation into chondrocytes, thus accelerating chondrogenesis and joint formation.^{15,16} In recent years, GDF-5 has shown great application potential in bone tissue repair. GDF-5 deficiency resulted in delayed bone healing,¹⁷ whereas its addition promoted MSCs osteogenic differentiation and VEGF expression.^{18,19} More importantly, implants loaded with GDF-5 displayed no evidence of peri-implant bone remodeling or seroma formation *in vivo*,²⁰ indicating a potentially safer substitute for BMP-2. Therefore, GDF-5 is a potential candidate for bone tissue regeneration by enhancing osteogenesis and angiogenesis.

Calcium phosphate scaffolds have been widely used for bone regeneration due to their similarity to the inorganic component of human bones and excellent biocompatibility. In particular, biphasic calcium phosphate (BCP) composed of hydroxyapatite (HA) and β -tricalcium phosphate (β -TCP) has attracted increasing interest, because of its bioactivity and degradability. Recently, the addition of trace element (*e.g.* Si, Mg, Co, *etc.*) into calcium phosphate scaffolds has been reported to achieve multifunctional ceramics to meet increasingly complex clinical demands.^{21–23} These trace elements have been found to play an important role in modifying physicochemical properties and biological response of tissue-engineering scaffolds. Especially, Zn is regarded as an essential trace element in human skeletal development and exhibits an inhibitory effect on HA growth through decreasing lattice parameters and thermal stability.²⁴ Also, the incorporation of Zn^{2+} into various calcium phosphates has shown increased osteogenic differentiation of MSCs *in vitro* as well as new bone formation *in vivo*.^{25,26} In addition, Cu as a co-factor of many enzymes has been shown to stimulate endothelial cells migration and VEGF expression, and further enhance angiogenesis *in vivo*.^{27,28} Enhanced angiogenesis potential and antibacterial properties were observed when Cu^{2+} was doped into mesoporous bioactive glass.²⁹ These results indicated that calcium phosphate scaffolds incorporating Cu/Zn ions have interesting multifunctional properties that need further investigation for bone tissue engineering.

The above findings showed that synthetic scaffolds with multifunctional properties, including angiogenesis and osteogenesis capacities, could be developed by preparing Cu/Zn co-incorporated calcium phosphate scaffolds-derived GDF-5 sustained release system. To the best of our knowledge, there are no previous studies investigating the incorporation of metallic ions and GDF-5 into calcium phosphate scaffold for bone regeneration. Therefore, this study aimed both to prepare Cu/Zn co-incorporated calcium phosphate scaffolds with GDF-5

sustained release system and to investigate the combined effect of the metallic ions and GDF-5 on the scaffold cyto-compatibility. In particular, the effects of Cu/Zn co-incorporation on the physicochemical properties of calcium phosphate, the osteogenic differentiation and VEGF expression of cells were evaluated.

Experimental

Preparation of BCP scaffolds doped with Cu/Zn ions

Firstly, calcium deficient apatite powders co-doped with Cu/Zn ions were synthesized by a wet chemical precipitation method.³⁰ Briefly, a mixed solution of $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$, $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$ and sodium dodecyl sulfate (0.03 M) were prepared and added dropwise into $(\text{NH}_4)_2\text{HPO}_4$ solution under stirring at room temperature with a (Ca + Zn + Cu)/P molar ratio of 1.55. The pH of the solution was adjusted to 8 by adding ammonia solution. The reaction solution were further stirred for 4 h and aged for 24 h. The reaction precipitate was removed, rinsed with water and lyophilized. Different amounts of Ca^{2+} , Zn^{2+} and Cu^{2+} were added (Table 1). The porous scaffolds were fabricated using alginate hydrogel beads as porogen (see ref. 31 for detailed procedures) and then sintered at 1200 °C for 2 h to form ceramics. The corresponding scaffold products were named depending on increasing Cu/Zn content as P0, P1, P2 and P3, respectively.

In vitro release of ions from prepared scaffolds and ion extraction preparation

The release kinetics of ions from the porous scaffolds (P0, P1 and P2) were determined by immersing them in 3 ml buffer solution (50 mM Tris–NaCl buffer, pH = 7.4 or 50 mM sodium acetate buffer, pH = 5.8) and placed in a shaking water bath (37 °C, 80 rpm). At predetermined intervals, the supernatant was collected and stored at 4 °C, and the fluid was replenished. The collections were analyzed by inductively coupled plasma mass spectrometer (ICP-MS).

The ion extraction of scaffold P2 was prepared according to the International Organization for Standardization method (ISO 10993-12). Briefly, the scaffold was immersed into Dulbecco's modified eagle's medium (DMEM) at a mass/volume ratio of 0.1 g ml^{−1} at 37 °C for 24 h. The supernatant was collected, filter-sterilized and stored at 4 °C for further use. In parallel, culture medium with appropriate concentration of Zn^{2+} (1 $\mu\text{g ml}^{-1}$) or Cu^{2+} (0.7 $\mu\text{g ml}^{-1}$) according to the ions release profiles were prepared as the control medium.

Table 1 Samples prepared using different concentrations of reaction reagents and the mass fraction ratio of β -TCP/HA calculated from X-ray diffraction spectrum

Scaffold products	Ca (M)	Cu (M)	Zn (M)	Ratio (β -TCP/HA)
P0	0.85	—	—	59/41
P1	0.84	0.005	0.005	64/36
P2	0.81	0.02	0.02	70/30
P3	0.75	0.05	0.05	—

Attachment of GDF-5-loaded microspheres onto ions-doped BCP scaffolds

First, GDF-5-loaded microspheres were prepared using the water-in-oil-in-water technique with polyvinyl alcohol (PVA) as the emulsifier.³² Briefly, 10 mg PLGA (M_w : 20 000, lactide: glycolide = 75 : 25; Daigang Biotech, China) was dissolved in 1 ml dichloromethane (DCM) as the oil phase. GDF-5 was dissolved in deionized water and emulsified in the oil phase to form emulsion. This emulsion was added dropwise into 100 ml water containing 1 g PVA and homogenized on an ice water bath (1000 rpm, 5 min). After removal from the bath, the emulsion was stirred at 300 rpm for 4 h to allow DCM to evaporate. The formed microspheres were then collected by centrifugation, rinsed with deionized water and lyophilized.

Second, the obtained microspheres were attached onto porous scaffold (P2) by vacuum (10 Pa) drying. Briefly, 5 mg microspheres were dispersed in 1 ml water and the suspension was pipetted onto the scaffold. The scaffold was placed in an evacuated desiccator for 2 h and stored at $-20\text{ }^{\circ}\text{C}$ for further use. The GDF-5-loaded scaffold was termed P2/GDF-5.

In vitro release of GDF-5 from scaffolds

Three scaffolds loaded with GDF-5 microspheres (P2/GDF-5) were each immersed in 2 ml phosphate-buffered saline (PBS) and placed in shaking bath ($37\text{ }^{\circ}\text{C}$, 100 rpm) for 30 days. At predetermined times, 1 ml supernatant was collected and quantified using enzyme-linked immunosorbent assay (ELISA) kit (Cusabio Biotech, Co. Ltd., China) according to the manufacturer's instructions. Then, fluid media was replenished after each removal.

Characterization of the prepared scaffolds

The morphology and composition of the samples were analyzed by scanning electron microscopy (SEM, JEOL JSM7001F) equipped with an energy dispersive X-ray (EDX) spectrometer. The phase structures were analyzed by X-ray diffraction (XRD, X'PertPro MPD, $\text{CuK}\alpha$, 35 mA, 45 kV) and Fourier transform infrared spectroscopy (FTIR, Nicolet 5700). The amount of ions released from scaffolds was analyzed by ICP-MS (NexION 350X, Perkin Elmer). The specific surface area was analyzed by nitrogen adsorption method (Gemini VII 2390, Micrometrics). The surface chemical composition was investigated using X-ray photoelectron spectrometer (XPS, XSAM800, Kratos) equipped with $\text{Mg K}\alpha$ radiation (12 kV and 12 mA).

In vitro cellular biocompatibility

To simulate the real environment of tissue repair process *in vivo*, the prepared scaffolds were evaluated using the co-culture system of bone mesenchymal stem cells (BMSCs) and vascular endothelial cells (VECs). BMSCs and VECs were purchased from Typical Culture Preservation Commission Cell Bank, Chinese Academy of Sciences (Shanghai, China), and cultured according to previous research reports.^{33,34} After 3–5 passages, BMSCs and VECs were mixed at a 1 : 1 ratio in a 1 : 1 mixture of endothelial

basal medium and DMEM.³⁵ The cells with a density of 1×10^5 per scaffold were seeded and co-cultured into the scaffolds.

To investigate cell morphologies on scaffolds, after culturing for 5 days, the scaffolds were removed and fixed in 2.5% glutaraldehyde solution for 1 h, followed by dehydration in a graded ethanol series (70, 80, 90 and 100%). Then, the samples were coated with gold and observed by SEM. In addition, the cells seeded on the scaffolds were fixed in 4% paraformaldehyde solution for 5 min, followed by incubation in PBS containing 2-(4-amidinophenyl)-6-indolecarbamidine dihydrochloride (DAPI, 100 ng ml^{-1}) for 5 min. Following thorough rinsing in PBS, the cells on scaffolds were observed using a fluorescence microscope (DMIL, Leica, Germany). The images were processed and quantified using Image Pro Plus software (IPP, Media Cybernetics, USA).

After 1, 4 and 7 days of culture, the cell proliferation activity was determined by Cell Counting Kit-8 (CCK-8, Dojindo, Japan) assay according to the manufacturer's instructions. The cell alkaline phosphatase (ALP) activity was quantitatively determined after 7 and 14 days of culture using an ALP microplate test kit (QuantiChrom™ alkaline phosphatase assay kit, Bioassay Systems, CA, USA) according to the manufacturer's instructions.⁵

To evaluate the gene expressions of ALP, osteopontin (OPN), osteocalcin (OCN) and osterix (OSX), polymerase chain reaction (PCR)-based technology was applied according to our previous report.³⁶ Total cell RNA was extracted from the co-cultured cells at day 14 using TRIzol reagent (Invitrogen, USA) as specified by the manufacturer. All experiments were performed in triplicate for yield validation. The relative expression levels of genes were examined using the Gene Genius program by normalizing with glyceraldehyde-3-phosphate-dehydrogenase (GAPDH) gene as an endogenous control.

Moreover, the effects of the prepared scaffolds on VEGF expression were investigated by ELISA analysis. Briefly, after co-culture of BMSCs and VECs (1×10^5 cells per ml) in the prepared scaffolds for 14 days, the supernatants were collected and quantified using ELISA kits (R&D Systems, Inc., Minneapolis, MN, USA) according to the manufacturer's instructions.

Statistical analysis

The statistical analysis was performed by SPSS software (SPSS Inc., Chicago, IL, USA) using non-parametric Kruskal–Wallis test. All the data were expressed as means \pm standard deviation (SD). A p -value < 0.05 was considered to be statistically significant.

Results

Characterization of the prepared scaffolds

SEM analysis showed that all the types of scaffolds had interconnected porous structures with a similar macropore size ranging from 200–600 μm (Fig. 1A). High magnification images (Fig. 1B) showed that the surface of the scaffold P0 was composed of smooth crystalline grains (size: $\sim 1\text{ }\mu\text{m}$) when no dopant was added. When the adding dopant concentration was

Fig. 1 SEM images showing the microstructure and morphology of various scaffolds: (A) $\times 100$, (B) $\times 10\text{ K}$; the elements distribution on the surface of (C) the scaffold P0 and (D) scaffold P2.

0.005 M, cubical nanoparticles (size: $\sim 200\text{ nm}$, shown in the white square) appeared on the smooth grains of the scaffold P1. When the adding dopant concentration was further increased to 0.02 M, the scaffold P2 surface turned to rough microparticles (size: $0.5\text{--}10\text{ }\mu\text{m}$). Further increase of the adding dopant concentration to 0.05 M resulted in the formation of prism particles (size: $\sim 8\text{ }\mu\text{m}$, shown in the white square) growing on the nanoflakes film of the scaffold P3. EDS analysis indicated that a small amount of Cu and Zn were uniformly dispersed on the surface of the scaffold P2 (Fig. 1D), whereas only Ca and P (P2) were observed for the scaffold P0 (Fig. 1C). In addition, the specific surface area of the scaffolds prepared at different dopant concentrations (0, 0.005, 0.02 and 0.05 M) were 0.57, 0.81, 0.99 and $0.38\text{ m}^2\text{ g}^{-1}$, respectively.

The crystal phases of all samples determined by XRD were shown in Fig. 2a. When the adding dopant concentrations were $< 0.05\text{ M}$, the XRD spectra of the samples (P0, P1 and P2) showed similar patterns, except for the difference in the relative intensities of HA/ β -TCP phase. With the progressive increase of adding dopant, the peak of (2 1 1) at 31.8° attributed to HA decreased in relative intensity. When the adding dopant concentration was 0.05 M, the sample P3 showed peaks of β -

TCP, but almost no HA peaks were observed. The mass fraction ratio of β -TCP/HA in the samples was calculated using the ratio of $I_{\text{TCP}}/I_{\text{HA}}$, where I_{TCP} and I_{HA} represent the normalized integrated intensity of β -TCP (0 2 10) peak at 31.1° and HA (2 1 1) peak, respectively.³⁷ The ratio values were shown in the Table 1. With the increase of adding dopant concentration, the mass fraction of β -TCP increased, whereas that of HA decreased. When the dopant concentration was 0.05 M, the product consisted of pure β -TCP phase.

The FTIR spectra (Fig. 2b) of the samples showed the characteristic peaks of calcium phosphate. When the adding dopant concentrations were $< 0.05\text{ M}$, for the samples (P0, P1 and P2), the peaks at 571 , 603 , 1045 and 1091 cm^{-1} were attributed to phosphate bands in HA,³⁸ while the peaks at 551 , 603 , 942 , 970 , 1015 and 1122 cm^{-1} were attributed to the band shoulders of β -TCP.³⁹ When the adding dopant concentrations were 0.05 M, the splitting peaks of sample P3 at 571 cm^{-1} disappeared, indicating the formation of pure β -TCP.

Elemental analysis of the products was performed using an XPS (Fig. 2c). The main peaks observed for the samples (P0, P1 and P2) contained Ca2p (346.9 eV), P2p (132.9 eV), P2s (190.5 eV), O1s (530.8 eV) and C1s (284.6 eV). For the samples P1 and P2, almost no Cu or Zn peaks were observed. Whereas, in addition to the main peaks for Ca2p (347.1 eV), P2p (133.1 eV), P2s (190.5 eV), O1s (531.1 eV) and C1s (284.6 eV), additional Cu2p (933.9 eV) and Zn2p (1022.3 eV) peaks were both detected for the sample P3.

The release kinetics of metallic ions from the prepared scaffolds

The ion concentration measurements in neutral buffer showed that both Cu and Zn exhibited a sustained and controlled release profile from the samples P1 and P2 over a time duration of one month (Fig. 3a and b). The cumulative release of Cu and Zn from sample P2 showed a significantly higher tendency than that from sample P1. In addition, the sustained release profile of Ca was detected from all the samples (P0, P1 and P2), with Ca cumulative release from samples P1 and P2 significantly faster than that from sample P0 (Fig. 3c). Moreover, the cumulative release of Cu, Zn and Ca from sample P2 in acidic buffer was significantly higher in comparison with that in neutral buffer (ESI Fig. S1†). The cumulative release of Cu and Zn at pH = 5.8 reached approximately 32% after 30 days, while only

Fig. 2 (a) XRD patterns, (b) FTIR spectra and (c) XPS spectra of various scaffolds.

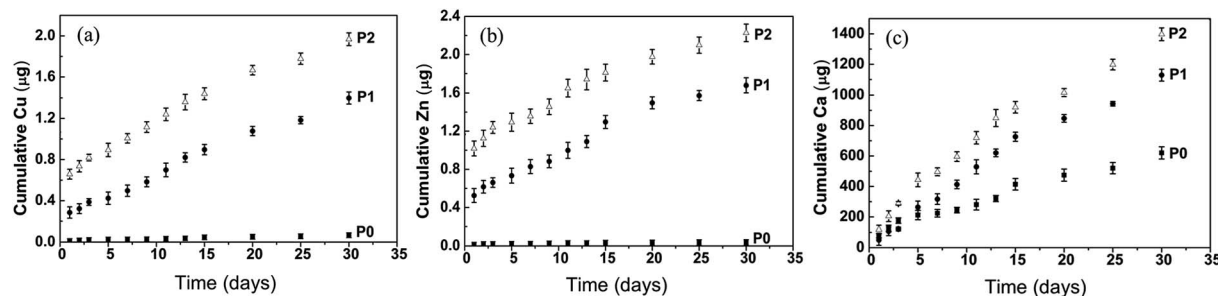

Fig. 3 Metallic ions release from various scaffolds in Tris–NaCl buffer: (a) Cu, (b) Zn and (c) Ca ions release from scaffolds P0, P1 and P2.

approximately 19% at pH = 7.4 (ESI Fig. S1a and b†). Additionally, the cumulative Ca release at pH = 5.8 reached approximately 15% after 30 days, while only approximately 2% at pH = 7.4 (ESI Fig. S1c†).

The morphology of GDF-5-loaded microspheres and GDF-5 release kinetics from the BCP scaffolds

The GDF-5-loaded microspheres were spherical in shape and 3–20 μm in diameter (Fig. 4a). Also, some residual emulsifier was observed on microsphere surface (Fig. 4a1). After dispensing as a suspension in scaffolds by vacuum drying, the microspheres were well-dispersed and immobilized onto the scaffold surface (Fig. 4b and b1). The profiles of GDF-5 release from the scaffold showed an initial burst release (~34%) during the first 2 days, followed by a relative slower release during the next 8 days, and thereafter by a steady release up to 30 days (Fig. 4c). The cumulative release reached approximately 74% after 30 days.

Fig. 4 SEM images of PLGA microspheres loaded with GDF-5: (a) $\times 500$, (a1) $\times 5$ K; SEM images of the scaffold P2 loaded with PLGA microspheres: (b) $\times 100$, (b1) $\times 1$ K; (c) the cumulative release profile of GDF-5 from the scaffold P2.

In vitro cell response of the prepared scaffolds

To evaluate the growth behavior of BMSCs and VECs on the prepared scaffolds, after co-culture for 5 days, the cell attachment and morphology on the scaffolds were observed by SEM and fluorescent staining (Fig. 5). The fluorescent images showed that cells were distributed along the pore wall of the scaffolds and the statistical analysis (not shown) found that cell densities on the ions-doped BCP scaffolds (P1 and P2) were significantly greater than that on pure scaffold (P0) (Fig. 5A). Comparatively, the highest cell density was observed on the ions-doped scaffolds loaded with GDF-5 microspheres. SEM images showed that cells on these scaffolds exhibited a well-spread morphology and cell density distributions on the various scaffolds were consistent with the fluorescent results (Fig. 5B). Notably, compared with cell adhesion on the surface of the scaffold P2, cells on the scaffold P2/GDF-5 fused and formed capillary-like structures.

In addition, cell proliferation was quantitatively determined using CCK-8 method, as shown in Fig. 6a. Cells proliferation on all types of scaffolds increased with the culture time. On day 1, there were no significant differences between the four groups. On days 4 and 7, cell proliferations on scaffolds P2 and P2/GDF-5 were significantly greater than on scaffolds P0 and P1. Furthermore, cell proliferation had an increase tendency on the scaffold P2/GDF-5 compared with the scaffold P2, but no significant difference was observed. Additionally, the ALP activity of cells was measured and shown in Fig. 6b. The ALP activity of cells on all types of scaffolds continually increased over 14 days. On days 7 and 14, the ALP activities of cells on scaffolds P2 and P2/GDF-5 were

Fig. 5 (A) Fluorescence images of cells cultured on various scaffolds and (B) SEM images of cell attachment on various scaffolds.

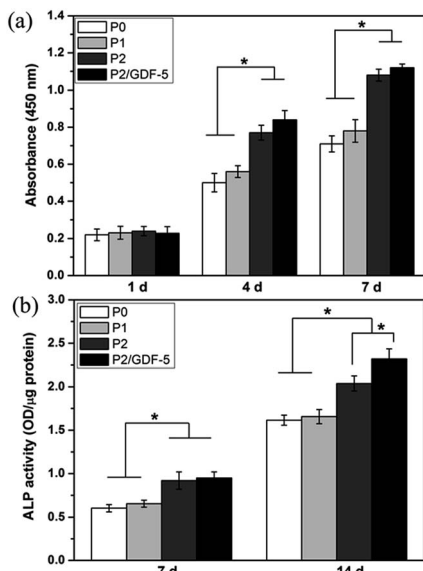

Fig. 6 (a) The proliferation and (b) ALP activity of cells cultured on various scaffolds. * indicates significant difference between the groups ($p < 0.05$).

significantly greater than those on scaffolds P0 and P1. Furthermore, on day 14, cells cultured on the scaffold P2/GDF-5 had a significantly greater ALP activity compared with those on the scaffold P2.

We also investigated the effects of various scaffolds on the expressions of cell bone-related genes. RT-qPCR analysis (Fig. 7) showed that on day 14, ALP, OCN and OSX expressions of cells on ions-doped scaffolds (P1 and P2) were significantly greater than on the pure scaffold (P0) (Fig. 7a, c and d), whereas there was a slight increasing trend for OPN expression between the groups (Fig. 7b). Furthermore, ALP and OSX expressions of cells on the scaffold P2 were significantly greater than on the scaffold P1. In addition, ALP, OPN and OCN expressions of cells on scaffold P2/GDF-5 were significantly greater than on the scaffold P2, whereas no significant difference was observed for OSX expression.

Fig. 8 VEGF secretion by cells cultured on various scaffolds for 14 days. * indicates significant difference between the groups ($p < 0.05$).

In addition, ELISA analysis (Fig. 8) showed that the ions-doped scaffolds (P1 and P2) significantly improved VEGF secretion compared with the pure scaffold (P0). The VEGF secretion amount increased with the adding dopant concentration. Moreover, VEGF secretion of cells on the scaffold P2/GDF-5 was significantly higher than that on the scaffold P2.

Discussion

In spite of substantial advances in bone tissue engineering, vascularization remains a major challenge that restricts the clinical application of large bone grafts. Synthetic scaffolds capable of accelerating osteogenesis and angiogenesis are regarded as an effective solution.⁴⁰ The main objective of this study was the incorporation of Cu/Zn ions into BCP scaffolds capable of GDF-5 sustained delivery to obtain novel multi-functional scaffolds for bone regeneration. The prepared BCP scaffolds had macropores ranging from 200–600 μm and showed good interconnectivity, which met the requirements for vascular and cell/bone ingrowth.⁴¹ In addition to an appropriate pore structure, Cu^{2+} and Zn^{2+} were co-doped into BCP scaffolds with the expectation of enhancing angiogenesis and osteogenesis simultaneously. When no dopant was added, the scaffold surface was smooth, similarly to a previous study on the pure BCP ceramic surface.⁴² In comparison, with an increase in adding dopant concentration, the scaffold surface tended to change from smooth grain crystalline (P0), to nanoparticles growing onto the smooth grain (P1), to rough microparticles (P2) and further to nanoflakes film (P3). Huang *et al.*⁴³ found that the co-substitution of Cu/Zn ions in HA coating on pure Ti resulted in HA morphology variation from needle to flaky. Previous studies indicated that the metallic ions could non-uniformly incorporate into the crystal surface and further change crystal morphology.^{44,45} In addition, the radii of Cu^{2+} and Zn^{2+} are both smaller than that of Ca^{2+} , which easily coordinate at Ca sites in the crystal structure. Therefore, we speculated that these morphological variations might be due to the effects of ion substitutions on the structure and growth of calcium phosphate crystals. Moreover, combining the results of XRD, FTIR and XPS (Fig. 2), it was concluded that with the increase of adding dopant concentration, the mass fraction of β -TCP increased while that of HA decreased. When the dopant

concentration was 0.05 M, the product consisted of pure β -TCP phase. This indicated that adding dopants reduced the thermal stability of calcium phosphate at high temperature and resulted in the decomposition of HA to β -TCP. Because ion release behavior correlated with its biofunction *in vivo*, BCP scaffolds were immersed into buffer solution to investigate the release kinetics of metallic ions. As Tris-NaCl and sodium acetate buffer solutions do not contain calcium or phosphate ions, therefore ion dissolution was favored over re-precipitation. The ion concentration measurements indicated that the increase of the β -TCP mass fraction led to the accelerating degradation of the BCP scaffold, thus facilitating the release of Cu/Zn ions. Moreover, pH decrease accelerated BCP degradation and metallic ions release. Therefore, the incorporation of Cu/Zn into the calcium phosphate scaffold was beneficial to sustained release of Cu/Zn ions. Subsequently, the microspheres were attached onto the scaffold surface by a vacuum-drying method. This simple room-temperature attachment method was also used to load PLGA microspheres onto Ti porous surface in our previous report.³² According to the investigation on the attachment stability and mechanism,³² it was concluded that the residual adhesive on the microsphere surface played a key role in the attachment of microspheres onto the scaffold. Also, the sustained release of GDF-5 further showed that the Cu/Zn co-incorporated BCP scaffold-derived GDF-5 release system was successfully fabricated.

Since angiogenic and osteogenic processes are triggered *via* the interaction between endothelial cells and bone-forming cells,⁴⁶ the cytocompatibility of the scaffolds was evaluated by direct co-culturing with BMSCs and VECs in accordance with the report by Kang *et al.*³⁵ Cell attachment is a key process affecting their proliferation and following function to form new tissue. The cell morphological observations (Fig. 5) found that the co-cultured cells distributed well and displayed flattened morphology on the walls of the pores, indicating the good cytocompatibility of these scaffolds. Notably, cells on the scaffold P2/GDF-5 formed capillary-like structures, confirming the good angiogenesis-inducing capacity of the scaffold P2/GDF-5. Combining the results of fluorescent image analysis and CCK-8 measurement, it was concluded that the addition of Cu/Zn ions and GDF-5 favored the cells proliferation. Several studies have proven that Cu^{2+} can promote endothelial cells proliferation,^{28,46} while Zn^{2+} can promote MSCs proliferation.⁴⁷ Moreover, GDF-5 was found to enhance MSCs proliferation in a dose- and time-dependent manner.⁴⁸ Therefore, the combination of Cu/Zn ions and GDF-5 probably played a synergistic role in cell proliferation when co-culture of BMSCs and VECs was performed. Noteworthy, the variation of physical structure of the scaffold surface might affect the cell attachment and proliferation according to previous studies.^{49,50}

One of the objectives of adding Cu/Zn ions and GDF-5 into BCP scaffolds was to enhance its osteogenesis capacity. ALP activity is regarded as a factor for the early stage of differentiation to mature osteoblasts, and bone forming-related genes including ALP, OPN, OCN and OSX are biochemical markers for osteogenic differentiation. In this study, on day 14, the ALP activity and the expressions of bone forming-related genes (ALP,

OPN and OCN) of cells on scaffold P2/GDF-5 were both significantly greater than those on scaffold P2, while ALP activity and the gene expressions of ALP and OSX of cells on scaffold P2 were significantly greater than those on scaffolds P0 and P1 (Fig. 6 and 7). Therefore, it was speculated that the additions of GDF-5 and appropriate concentrations of Cu/Zn ions played an important role in enhancing ALP activity and osteogenic gene expressions. GDF-5 was proved to stimulate osteogenic differentiation by enhancing both ALP activity and mineral formation *in vitro*.^{18,51} Also, relative study showed that the gene expressions of Runx2 and OCN were enhanced by GDF-5 addition in a dose-dependent manner.⁵² Our results are in accordance with these studies, indicating that GDF-5 may have a positive role in osteogenesis. Moreover, with the dopant concentration increasing, the increase of mass fraction of β -TCP indicated that the scaffold became more soluble and favored Cu/Zn ions release. Previous studies have shown that Zn^{2+} at appropriate concentrations does stimulate the osteogenic differentiation of BMSCs, whereas Cu^{2+} may not play any role in osteogenic differentiation.^{53,54} To confirm these findings, the extraction medium of the scaffold P2 was co-cultured with BMSCs. After 21 days of co-culture of BMSCs and extraction medium, calcium deposition was stained with 1% Alizarin Red S (Sigma-Aldrich, USA). The preliminary results (ESI Fig. S2†) showed that the amounts of mineral formation in the extraction medium as well as Zn^{2+} -added culture medium were significantly greater than those in the blank culture medium or Cu^{2+} -added culture medium. The results indicated that Zn^{2+} played a positive role in osteogenesis when released from the scaffold. Also, this is in agreement with the evidence found in the literature showing that Zn^{2+} has a greater osteogenic capacity than Cu^{2+} .⁵⁵ Based on the above analysis, we concluded that GDF-5 and Zn^{2+} played a combined effect on enhancing the osteogenesis capacity of BCP scaffold.

Another objective of this study was to enhance the angiogenesis capacity of the scaffold. It is well known that angiogenesis is mediated by the coordinated action of various growth factors, especially VEGF is regarded as an important angiogenic stimulator.⁵⁶ VEGF can promote endothelial cells migration and proliferation, and the formation of tubular structures or vessels, finally accelerating tissue repair. In this study, the VEGF secretion level increased with the adding dopant concentration and reached a maximum when GDF-5 was added (Fig. 8), suggesting the angiogenic potential of Cu/Zn ions and GDF-5. Zeng *et al.*⁵⁷ found that GDF-5 promoted the angiogenesis of MSCs by up-regulation of VEGF expression. Moreover, GDF-5 addition was proved to significantly enhance blood vessel formation compared with BMP-2 *in vivo*.⁵⁸ Our finding of enhanced VEGF expression was consistent with these results. In this study, PLGA microspheres were successfully attached onto the scaffold surface and exhibited a sustained GDF-5 release (Fig. 4). The controlled release of GDF-5 with better retention significantly prolonged the osteogenesis and angiogenesis capacities of the BCP scaffold. In addition, studies have proved that an appropriate concentration of Cu^{2+} can stimulate the angiogenesis of VECs *via* stimulating VEGF secretion and up-regulating

downstream signalling events.⁵⁹ To evaluate the angiogenesis capacity of the ions released from the scaffold, the extraction medium of the scaffold P2 was co-cultured with VECs. VECs were seeded onto Matrigel (Sigma Aldrich)-coated wells. After 12 h, the cells cultured with the extraction medium as well as Cu²⁺-added culture medium formed capillary-like structures, whereas no capillary-like structure formed in the blank culture medium or Zn²⁺-added culture medium (ESI Fig. S3†). The results indicated that Cu²⁺ had greater angiogenic capacity than Zn²⁺ and played a leading role in enhancing angiogenic capacity of the BCP scaffold. As the combination of ion dopants and GDF-5 resulted in the highest VEGF secretion level, it was concluded that GDF-5 and Cu²⁺ might have a synergistic action on enhancing the angiogenic capacity of the BCP scaffold.

According to the results above, we concluded that the incorporation of Cu/Zn ions into BCP scaffolds exerted a positive influence not only on osteogenic differentiation, but also on angiogenesis *in vitro*. Moreover, the addition of GDF-5 further promoted the osteogenic and angiogenic capacities of Cu/Zn co-doped BCP scaffold. Although the interaction mechanism of the metallic ions and GDF-5 is unclear, our results do suggest that Cu/Zn ions and GDF-5 have a combined effect on osteogenesis and angiogenesis. Therefore, the Cu/Zn co-incorporated calcium phosphate scaffolds-derived GDF-5 sustained release system has a promising potential to be used as a superior candidate for bone regeneration. Moreover, the *in vivo* compatibility of the scaffold will be investigated in our following research.

Conclusion

In this study, Cu/Zn co-incorporated BCP scaffolds combined with GDF-5 sustained release system were successfully prepared. With the increase of adding dopant concentration, the surface micromorphology of the scaffolds changed from smooth grain crystalline to nanoflakes film, accompanying by an increase of the mass ratio of β -TCP/HA. The results suggested that Cu/Zn co-incorporation played an important role in the morphogenesis and phase composition of the BCP scaffold. Additionally, GDF-5-loaded PLGA microspheres were successfully attached onto the BCP scaffold surface and exhibited a sustained release. *In vitro* cell culture revealed that Cu/Zn co-doped BCP scaffold exhibited a combined effect of both angiogenic and osteogenic capacities. Moreover, the sustained release of GDF-5 further enhanced osteogenic and angiogenic capacities of ions-doped BCP scaffold. Although the active mechanism of the metallic ions and GDF-5 on cell behavior remains unclear, the Cu/Zn co-incorporated BCP scaffold-derived GDF-5 sustained release system provides a promising method for fabricating multifunctional scaffolds with improving angiogenic and osteogenic capacities.
