A gold nanoparticle based colorimetric and fluorescent dual-channel probe for acetylcholinesterase detection and inhibitor screening†

Jie Lv, Binnan He, Na Wang, Meng Li* and Yulong Lin*

Introduction

Acetylcholine (ACh), as a central neurotransmitter, plays a decisive role in memory and learning.1,2 It has been reported that Alzheimer’s disease (AD), the most common form of dementia in elderly people, is related to a low level of ACh in the brain.3,4 The hydrolysis of ACh catalyzed by acetylcholinesterase (AChE) at cholinergic synapses can cause the termination of synaptic transmission. Furthermore, much research has provided evidence that AChE can also accelerate the aggregation of amyloid-β peptide making a further contribution to the progression of AD.5–7 Therefore, sensitive and quantitative detection of AChE activity and screening of its inhibitors are of diagnostic importance and have therapeutic implications.

To this end, a range of methods/techniques for detection of AChE level have been employed, including the colorimetric Ellman method8,9 or the detection of hydrogen peroxide (H₂O₂) produced by oxidation of choline.10,11 With the development of H₂O₂ sensors,12–14 recently, fluorescent or colorimetric approaches based on synthetic probes and nanozymes,15–18 as well as various electrochemical methods,19,20 have been developed to monitor AChE activity and screen the inhibitors of AChE. However, most of these methods cannot discriminate AChE from other biothiols. The poor sensitivity and low specificity make them unsuitable for biological sample analysis.

Due to the distinctive physical and optical properties, gold nanoparticles (AuNPs) have been successfully employed as a colorimetric probe for the detection of AChE activity based on their size-dependent surface plasmon resonance absorption.21–23 Although promising, the aggregation of AuNPs in most of these methods was caused by salt-sensitive electrostatic interaction. The electrostatic interaction is not stable in physiological environment, since some biomacromolecules in vivo might also compete for the interactions with the molecules on the surface of nanoparticles. Supramolecular host–guest interaction has played an important role in the chemical sensing research, including the sensor chip for the metal ion detection24,25 and the fluorescent DNA detection.26,27 The use of host–guest interactions is an attractive alternative to electrostatic interaction since the recognition motifs are specific and bio-orthogonal without an additional catalyst, which is suitable for biological application.

Herein, a new dual-signalling sensing strategy based on the competitive host–guest interaction between p-sulfonatocalix[6]arene (p-SC₆A) capped AuNPs and Rhodamine B (RhB)/acetylthiocholine, a fluorescent and colorimetric dual channel probe was developed for rapid detection of AChE with high sensitivity and selectivity. The detection limit was estimated to be 0.16 mU mL⁻¹. Crucially, due to the specific host–guest interaction, the high selectivity of the bioassay permitted the discrimination of AChE from other cations and proteins including biothiols and enzymes. Furthermore, the present method was also successfully applied to determine AChE levels and screen AChE inhibitors in real cerebrospinal fluid (CSF) samples, which suggested that our proposed method has great potential to be applied in monitoring the disease progression and drug treatment effects of Alzheimer’s disease (AD).
when interacting with p-SC6A. More importantly, through binding with p-SC6A, the RhB molecules are closely associated with AuNPs which would enhance the quenching efficiency of RhB. Upon addition of ATC into the RhB-p-SC6A-AuNPs solution, the RhB molecules existed inside the p-SC6A host can be replaced by ATC, leading to the recovery of the fluorescence. When AChE was introduced, ATC could be hydrolyzed by AChE to generate thiocholine. Thiocholine strongly binds onto surfaces of AuNPs via the formation of Au–S bond. At the same time, the quaternary ammonium group on thiocholine and the p-SC6A molecules attached on different AuNP surfaces may be able to interact via host–guest interaction and cause the aggregation of AuNPs and a release of RhB-p-SC6A, leading to a further recovery of RhB fluorescence. With the two types of reporters, the system can differentiate well between thiocholine and other biothiols and overcome the interference of salts effects, making it suitable for monitoring the level of AChE in the cerebrospinal fluid (CSF), which is relevant to the progression of AD (Fig. 1).3–7

**Experimental**

**Materials and measurements**

Gold(m) chloride trihydrate (HAuCl4·3H2O), Rhodamine B (RhB), sodium borohydride (NaBH4), acetylcholinesterase (AChE), chymotrypsin and glucose oxidase were obtained from Sigma-Aldrich. para-Sulfonatocalix[6]arene (p-SC6A) was purchased from TCI Development Co., Ltd. (Shanghai, China). Arginine, glutamic acid, tyrosine and threonine were obtained from Aladdin Reagent Inc. (China). All these reagents were used as received without further purification. Deionized water (18.2 MQ cm) used for all experiments was obtained from a Milli-Q system (Millipore, Bedford, MA).

A JASCO FP-6500 spectrophotometer was used to monitor the fluorescence of RhB. The slit width for the excitation and emission was 5 nm. The UV-vis absorption spectra of Au nanoparticles were recorded by a Jasco-V550 UV-vis spectrophotometer. Fourier transform infrared spectroscopy (FTIR) measurements were carried out with a BRUKER Vertex 70 FTIR spectrometer. The sample was prepared as pellets using spectroscopic grade KBr. Transmission electron microscopic (TEM) experiments were performed on a Philips Tecnai G2 20 S-TWIN microscope operating at 200 kV.

**Synthesis of p-SC6A capped AuNPs**

The p-SC6A-AuNPs were synthesized according to previous reports.29 Briefly, p-SC6A solution (2 mL, 10 mM) was mixed with deionized water (94 mL) under mild stirring at room temperature, and then HAuCl4 solution (2 mL, 26.3 mM) was added. After stirring for 20 min in the dark, freshly prepared NaBH4 solution (2 mL, 10 mM) was added into the above mixture solution immediately, and then the reaction was allowed to proceed for 2 h in the dark. The obtained p-SC6A-AuNPs were washed twice by centrifugation to remove the free p-SC6A. After that, p-SC6A-AuNPs were dispersed in deionized water and stored at 4 °C for further use.

**Synthesis of RhB-p-SC6A-AuNPs**

RhB (9.58 mg) was dissolved in deionized water (10 mL) to obtain the stock solution. Then different amounts of RhB stock solution were added respectively into the solutions of p-SC6A-AuNPs (5.5 nM) under stirring. The mixture was stirred continuously at room temperature for 2 h. After that, the fluorescence spectra of the mixture solutions were monitored with excitation at 550 nm. As the concentration of RhB increased, the fluorescence of the resulting solution was intensified. In a low concentration region (c = 0–2 μM), the very weak fluorescence observed in RhB-p-SC6A-AuNPs solutions, indicating that almost all the RhB molecules interacted with p-SC6A on the surface of AuNPs. However, the emission intensity increased when the concentration of RhB was greater than 2 μM. Therefore, we chose 2 μM as the optimal concentration of RhB to synthesize RhB-p-SC6A-AuNPs.

**Detection of AChE activity assay**

For the sensitivity of this assay, different levels of AChE were added to the PBS solution (10 mM, pH = 8.0) composed of ATC (20 μM) and RhB-p-SC6A-AuNPs (5 nm), followed by incubation at room temperature for 20 min to make the reaction between AChE and ATC sufficiently. After that, the absorption spectra and fluorescence spectra were monitored. For the selectivity of this assay, different biothiols, amino acids (final concentration of each biothiol or amino acid was 0.1 mM) or enzymes (final concentration of each enzyme was 1 U mL⁻¹) instead of AChE were added to the mixture of RhB-p-SC6A-AuNPs and ATC, respectively. The mixtures were incubated at room temperature for 20 min, and then their absorption spectra and fluorescence spectra were recorded.

**Evaluation for inhibitor assay**

For the inhibition assay, different concentrations of tacrine (an approved AChE inhibitor) were first premixed with AChE (50 mU mL⁻¹) for 30 min at 37 °C. Then, the pretreated AChE samples (The final concentration of AChE was 5 mU mL⁻¹) were mixed with RhB-p-SC6A-AuNPs and ATC. Finally, the reaction solution was allowed to stand at room temperature for 20 min. The absorbance of each sample was recorded using UV-vis spectroscopy. The inhibitory ratios (%) of tacrine was expressed as follows:
Inhibitory ratio (%) = \frac{\frac{A_{600}}{A_{520}} - \frac{A_{600}}{A_{520}}}{A_{600}} \times 100

where \(A_{600}/A_{520}\) was the ratio of the absorbance value at 600 nm to that at 520 nm in the presence of both the inhibitor and the enzyme, \(A_{600}/A_{520}\) was the ratio of the absorbance value at 600 nm to that at 520 nm with enzyme only. And \(A_{600}/A_{520}\) was the ratio of the absorbance value at 600 nm to that at 520 nm in the absence of the enzyme and inhibitor. The fluorescence of the system was also monitored, and the inhibitory ratio was calculated with the same method.

**Handing of mice**

Eight-week-old male C57BL6/J mice with body weights between 20 and 25 g were obtained from the Experimental Animal Center of the Chinese Academy of Medical Sciences. All the protocols and procedures for animal handling were carried out following the guidelines of the Hebei committee for care and use of laboratory animals, and were approved by the Animal Experimentation Ethics Committee of the Hebei Medical University. CSF was collected under anaesthesia using a glass pulled micropipette after exposure of the cisterna magna, taking care not to contaminate the CSF with blood. The CSF was immediately diluted 1:10 in phosphate buffered saline (PBS) and detected in one day after collection.

**Results and discussion**

**Synthesis and characterization of the Rhb-p-SC6A-AuNPs**

To develop this strategy, we first synthesized SC6A modified AuNPs using SC6A as the stabilizer. p-SC6A-AuNPs were mono-dispersed with average size of ~13 nm according to transmission electron microscopy (TEM) characterization (Fig. S1A†). The p-SC6A-AuNPs solution showed typical plasmon absorption around 520 nm (Fig. S2†). The modification of p-SC6A on the surface of AuNPs was evidenced by FTIR. As shown in Fig. S3,† the characteristic absorption peaks of SO3− at 1177 cm⁻¹ and 1113 cm⁻¹ found in pure p-SC6A, were shifted to 1155 cm⁻¹ and 1104 cm⁻¹, respectively, which suggested that the SO3− groups grafted onto the surface of AuNPs.28 Rhb-p-SC6A-AuNPs were prepared by mixing various concentrations of Rhb (0-4 μM) with p-SC6A-AuNPs (5.5 nM) solution under mild stirring. To identify an optimal concentration of Rhb that could be appended to p-SC6A-AuNPs, the fluorescence of the Rhb-p-SC6A-AuNPs solutions were monitored after equilibration for 2 h. As shown in Fig. S4,† the optimal concentration of Rhb would be 2 μM, when no excess Rhb was free in the solution and only very weak fluorescence was observed. Furthermore, complexed with Rhb could not change the absorption band of p-SC6A-AuNPs indicating no aggregation occurred during the functionalized procedure which was in accordance with the TEM image (Fig. S2 and S1B†).

**Quantitative detection of ATC by Rhb-p-SC6A-AuNPs**

To evaluate the sensing ability of Rhb-p-SC6A-AuNPs for ATC, the absorbance and fluorescence spectra of Rhb-p-SC6A-AuNPs in the presence of ATC were monitored (Fig. 2). Addition of ATC to the solution of AuNPs did not induce absorption spectral variation (Fig. S2†) but caused the release of Rhb to recover its fluorescence. The detection range of ATC was from 0.05 to 20 μM (Fig. 2B) and the linear relationship between corresponding fluorescence change (F/F₀) and ATC concentration was shown in Fig. 2B. The detection limit for ATC can be as low as 13 nM, which attributed to the sensitivity of this assay to detect AChE.

**Sensitivity of the assay for AChE detection**

AChE can catalyze its substrate ATC to generate thiocholine, which would lead to the aggregation of p-SC6A-AuNPs. For further determining the sensitivity of the protocol to monitor the activity of AChE, we first applied the AuNP-based colorimetric assay. Various amounts of AChE were added to the solution composed of ATC (20 μM) and Rhb-p-SC6A-AuNPs (5 nM) in PBS (10 mM, pH = 8.0), followed by incubation at room temperature for 20 min to make the reaction between AChE and ATC sufficiently. The aggregation process of AuNPs can be easily visualized by a colour change from red to purple with the naked-eye (Fig. 3A). Simultaneously, the UV/vis absorption spectra of the solutions were recorded. As indicated in Fig. 3A, as the concentration of AChE increased, the absorption around 520 nm gradually decreased along with an increase in intensity of the band above 600 nm (Fig. 3A), indicating the formation of AU NP aggregates. The aggregation process was also directly confirmed by TEM analysis (Fig. S5†).

It is worth noting that, at low AChE concentrations (0-5.0 mU mL⁻¹), the plot of A_{600}/A_{520} (the ratio of absorbance at 600 nm and 520 nm) versus the concentrations of AChE revealed a nearly linear relationship. The limit of detection of this assay was evaluated to be 0.46 mU mL⁻¹, which, to our knowledge, was much lower than most of the previous reported optical methods.22,23 The high sensitivity of our assay was raised from the specific host–guest interactions between the quaternary ammonium group on thiocholine and the p-SC6A molecules attached on different AuNP surfaces. The lowest detectable concentration of AChE was further determined via the fluorescence recovery of Rhb. As shown in Fig. 3E, the emission intensity enhancement rate (F/F₀) was fast at low AChE
than that of AChE, the corresponding solutions. (B) Variation of sensor for AChE. As shown in Fig. S7 threonine were also employed to evaluate the selectivity of the assay for AChE detection. To evaluate the specificity of this assay for AChE, we next measured the interference from other biothiols, amino acids, anions, cations or proteins especially those that were found abundantly in human body. With thiol group, biothiols, such as cysteine (Cys) and glutathione (GSH), could readily attach on the surfaces of AuNPs via Au-S bonds, which were quite similar to thiocholine. However, these biothiols even at high concentrations could not recovery the fluorescence of the dye because of the relative high binding affinity of p-SC6A to RhB (Fig. S6†). Furthermore, owing to the lacking of the positively charged quaternary ammonium group which could interact with p-SC6A on the surface of AuNPs, they were also unable to induce the aggregation of AuNPs (Fig. 4A). Several other enzymes, proteins or amino acids such as bovine serum albumin (BSA), chymotrypsin, glucose oxidase, arginine, glutamic acid, tyrosine and threonine were also employed to evaluate the selectivity of the sensor for AChE. As shown in Fig. S7† and 4B, for other amino acids or proteins with a concentration up to 100 times higher than that of AChE, the A600/A520 was almost unchanged compared with the control group, indicating that our assay displayed a high selectivity for AChE.

### Selectivity of the assay for AChE detection

To evaluate the specificity of this assay for AChE, we next measured the interference from other biothiols, amino acids, anions, cations or proteins especially those that were found abundantly in human body. With thiol group, biothiols, such as cysteine (Cys) and glutathione (GSH), could readily attach on the surfaces of AuNPs via Au-S bonds, which were quite similar to thiocholine. However, these biothiols even at high concentrations could not recovery the fluorescence of the dye because of the relative high binding affinity of p-SC6A to RhB (Fig. S6†). Furthermore, owing to the lacking of the positively charged quaternary ammonium group which could interact with p-SC6A on the surface of AuNPs, they were also unable to induce the aggregation of AuNPs (Fig. 4A). Several other enzymes, proteins or amino acids such as bovine serum albumin (BSA), chymotrypsin, glucose oxidase, arginine, glutamic acid, tyrosine and threonine were also employed to evaluate the selectivity of the sensor for AChE. As shown in Fig. S7† and 4B, for other amino acids or proteins with a concentration up to 100 times higher than that of AChE, the A600/A520 was almost unchanged compared with the control group, indicating that our assay displayed a high selectivity for AChE.

### Evaluation for inhibitor assay

Encouraged by the sensitivity and specificity of this assay, we next evaluated whether RhB-p-SC6A-AuNPs could be used to screen AChE inhibitors. As indicated in Fig. 5, pretreated AChE with tacrine, a well-known cholinesterase inhibitor, the aggregation of AuNPs was inhibited. The degree of AuNP aggregation was dependent on the concentration of tacrine. With the increase of tacrine concentrations, the colour of the solution changed from violet to wine red, corresponding to a decrease in A600/A520. The maximum inhibition ratio of tacrine was 89.63% with the IC50 value of 37.8 μM (Fig. 5B), which was in accordance with the previous reports. Similarly, the further fluorescence recovery of RhB was blocked with the presence of ATC (20 μM). Inset were the photographs of corresponding solutions. (B) Variation of A600/A520 versus the concentration of AChE for the solution of RhB-p-SC6A-AuNPs containing ATC (20 μM). (C) The linear region of (B). (D) The fluorescence emission spectra of RhB from RhB-p-SC6A-AuNPs by incubating with various concentrations of AChE in the presence of ATC (20 μM). Inset were the fluorescent images. (E) Calibration curve corresponding to Fp/F0 against the concentration of AChE from fluorescent assay. (F) The linear region of (E). Fp and F0 were the fluorescence intensities of RhB-p-SC6A-AuNPs containing ATC (20 μM) at 578 nm in the presence and absence of AChE, respectively.

### Absorbance spectra of RhB-p-SC6A-AuNPs that were incubated with different concentrations of AChE in the presence of ATC (20 μM). Inset was the photographs of corresponding solutions. (B) Absorption spectrum of RhB-p-SC6A-AuNPs containing ATC (20 μM). (C) The linear region of (B). (D) The fluorescence emission spectra of RhB from RhB-p-SC6A-AuNPs by incubating with various concentrations of AChE in the presence of ATC (20 μM). Inset were the fluorescent images. increased concentration of tacrine, which was caused by the reduced amount of thiocholine fluorescence recovery of RhB (Fig. 5C). The IC_{50} value of tacrine obtained from the fluorescence method was 34.01 μM (Fig. 5D), which was quite similar with that from the colorimetric assay. These results indicated that the two methods used to quantitate the inhibition of AChE with that from the colorimetric assay. These results indicated that the two methods used to quantitate the inhibition of AChE with that from the colorimetric assay. These results indicated that the two methods used to quantitate the inhibition of AChE with that from the colorimetric assay. These results indicated that the two methods used to quantitate the inhibition of AChE with that from the colorimetric assay.

Analysis of CSF samples

It was also necessary to determine whether our assay can be applied to screen AChE inhibitors and evaluate the efficiency. In conclusion, based on the competitive host–guest interaction between SC6A-AuNPs and RhB/quaternary ammonium group, a highly sensitive and selective assay for AChE detection was successfully established. With the dual signal reporters, our system can differentiate well between AChE and other proteins with a detection limit as low as 0.16 mU mL$^{-1}$. Furthermore, the present method was also successfully applied to determine AChE levels and screen AChE inhibitors in real CSF samples, which was significantly important for monitoring the disease progression and drug treatment effects for AD. Crucially, when change RhB to AChE inhibitor, our system can also be used as ACh or choline responsive-drug release system. Given its simplicity and easy operation, this method may extend to high-throughput screening of AChE inhibitors and be highly useful in a wide range of applications such as drug discovery, bio-analysis, and targeted drug delivery system.
