Synthesis and performance evaluation of nanostructured $NaFe_xCr_{1-X}(SO_4)_2$ cathode materials in sodium ion batteries (SIBs)

Umair Nisar, (1) †a Mona Hersi Gulied, †b R. A. Shakoor, (1) *a Rachid Essehli, c Zubair Ahmad, a Abdullah Alashraf, a Ramazan Kahraman, b Siham Al-Qaradawi (1) d Ahmed Soliman e

This research work focuses on the synthesis and performance evaluation of NaFe_xCr_{1-x}(SO₄)₂ (X = 0, 0.8 and 1.0) cathode materials in sodium ion batteries (SIBs). The novel materials having a primary particle size of around 100–200 nm were synthesized through a sol–gel process by reacting stoichiometric amounts of the precursor materials. The structural analysis confirms the formation of crystalline, phase pure materials that adopt a monoclinic crystal structure. Thermal analysis indicates the superior thermal stability of NaFe0_{.8}Cr_{0.2}(SO₄)₂ when compared to NaFe(SO₄)₂ and NaCr(SO₄)₂. Galvanostatic charge/discharge analysis indicates that the intercalation/de-intercalation of a sodium ion (Na⁺) into/from NaFe(SO₄)₂ ensues at about 3.2 V due to the Fe²⁺/Fe³⁺ active redox couple. Moreover, *ex situ* XRD analysis confirms that the insertion/de-insertion of sodium into/from the host structure during charging/discharging is accompanied by a reversible single-phase reaction rather than a biphasic reaction. A similar sodium intercalation/de-intercalation mechanism has been noticed in NaFe_{0.8}Cr_{0.2}(SO₄)₂which has not been reported earlier. The galvanostatic measurements and X-ray photoelectron spectroscopy (XPS) analysis confirm that the Cr²⁺/Cr³⁺ redox couple is inactive in NaFe_xCr_{1-x}(SO₄)₂ (X = 0, 0.8) and thus does not contribute to capacity augmentation. However, suitable carbon coating may lead to activation of the Cr²⁺/Cr³⁺ redox couple in these inactive materials.

1 Introduction

Due to the technological advancements in portable electronics, the demand for secondary batteries has increased considerably in the last decade.^{1,2} To date, the lithium ion battery system is considered one of the best candidates for portable energy storage applications due to its high-energy and power density.²⁻⁵ However, due to rapid technological advancements, the demand for high energy, high power, safer and cheaper batteries is increasing at a great pace.^{1,6-8} Therefore, new battery systems with promising chemistries are also being explored as an alternative to lithium ion batteries.⁹⁻¹¹

In the last decade, much research was devoted to the development of sodium ion batteries (SIBs) due to their similar electrochemical mechanism to lithium ion batteries. Also, the abundance of sodium resources in nature makes this technology much cheaper as compared to lithium ion batteries. ¹²⁻¹⁴ Unfortunately, due to the larger size of sodium ion (Na⁺) as compared to lithium (Li⁺), it is difficult to identify new compounds capable of reversibly intercalating Na⁺ at fast rates. Recently considerable efforts have been devoted to develop novel potential cathode materials for Na-ion batteries. ^{14,15} Towards this direction, several cathode materials have been identified such as Na₃V₂(PO₄)₃, NaTi₂(PO₄)₃, Na₄Fe₃(PO₄)₂(-P₂O₇), NaNiO₂, NaMnO₂, NaFePO₄, Na₂FeP₂O₇, Na₃V₂(PO₄)₂F₃, Na₄Co₃(PO₄)₂P₂O₇ demonstrating promising energy storage performance. ¹⁶⁻²⁴ However, to address the future needs, development of cheaper, safe and high-performance cathode materials is still challenging. ^{14,15,25}

Recently, NaFe(SO₄)₂ has been reported having promising electrochemical performance. This material intercalates/deintercalates sodium at (3.2 V) demonstrating charge/discharge capacity (80 mA h g⁻¹) with good rate capability and cyclability. Being impressed with the electrochemical performance of NaFe(SO₄)₂ and promising merits of chromium (Cr) such as (i) reasonable high voltage and (ii) structural stability, we decided to synthesize an offshoot of NaFe(SO₄)₂ by substituting iron (Fe) with chromium (Cr). In this study, we report the synthesis,

structural, thermal properties and electrochemical performance of NaFe_xCr_{1-X}(SO₄)₂, where (X = 0, 0.8 and 1.0). To the best of our knowledge, this is a comprehensive report which describes the sodium insertion/de-insertion mechanism and structural alter-

ation in NaFe_xCr_{1-x}(SO₄)₂ during the charging/discharging process.

2 **Experimental**

RSC Advances

Materials preparation

NaFe_rCr_{1-X}(SO₄)₂ where (X = 0, 0.8, 1.0) was synthesized by a sol-gel process using sodium nitrate, iron nitrate nonahydrate, chromium nitrate and ammonium sulfate (Sigma Aldrich) in stoichiometric ratios. Firstly, all the precursors were dissolved in 100 ml of distilled water with continuous stirring at around 50 °C. After 2 hours of continuous stirring, the temperature was raised to 70 °C and the solution was evaporated until a clear transparent gel was formed. The resulting gel was dried in a conventional oven at around 120 °C for 6 hours. Later, the gel was homogeneously ground into fine powder and then calcined at 420 °C for 6 hours in air to form pure NaFe_xCr_{1-X}(SO₄)₂ (X = 0, 0.8, 1.0). During the calcination process, the heating/cooling rates were set at 5 °C per minutes to ensure the formation of phase pure crystalline materials. A schematic diagram of the synthesis process is presented in Fig. 1.

2.2 Structural characterization

Powdered XRD (Panalytical diffractometer) using Cu-Kα radiations was used to identify the phase purity and structural details of the synthesized materials. The data were collected over the 2θ angular range of 10-90° with a step size of 0.01°. The morphology (particle size, shape, distribution) and elemental mapping of the synthesize materials were under taken using scanning electron microscopy (SEM, NOVA NANOSEM 450). Thermal stability of the synthesized materials was studied using thermogravimetric analysis (Perkin Elmer, TGA 4000) from room temperature to 500 °C at the heating rate of 10 °C in a N2 atmosphere. Fourier-transform infrared spectroscopy (Perkin Elmer Frontier FT-IR) was further used to confirm the phase purity using KBr pellet method in the range of 500-2500 cm⁻¹ wave numbers. The activity of redox couples was studied through X-ray Photoelectron spectroscopy (XPS) (Thermo-Scientific-Sigma Probe).

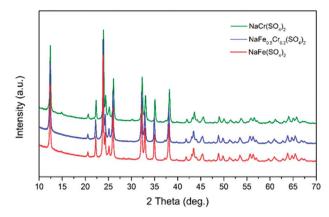

Fig. 2 XRD patterns of pristine NaFe(SO₄)₂, NaFe_{0.8}Cr(SO₄)₂ and NaCr(SO₄).

Electrochemical characterization 2.3

The cathodes were fabricated by forming a slurry composed of 70 wt% active material NaFe_xCr_{1-X}(SO₄)₂, 20 wt% conductive carbon (super-P) and 10.0 wt% polyvinylidene fluoride binder in 1-methyl-2-pyrrolidone (NMP). The slurry was homogeneously mixed for 10 hours and was later cast on an aluminum foil using a doctor blade. The cast electrode sheet was dried in a conventional oven for 6 hours to remove NMP. The dried cathode sheet was then rolled using a rolling machine for good compaction and then was dried in a vacuum oven for 12 hours to remove the last traces of water. The electrodes of 14.0 mm diameter were punched from vacuum dried cathode sheet and later shifted to the glove box for cell fabrication. Electrochemical measurements were performed by fabricating 2032-type coin cells in an Ar-filled glove box. Sodium metal was used as the negative electrode. The electrolyte was composed of 1 M NaClO₄ dissolved in ethylene carbonate (EC) and 2.0 wt% of fluoroethylene carbonate (FEC). Galvanostatic charge/discharge tests were performed using WonAtech battery cycler (WBSC 3000L, Korea) in the voltage range of 1.5-4.5 V at room temperature.

3 Results and discussion

The structural properties and phase purity of the synthesized phases was studied through XRD analysis. The XRD patterns of pristine NaFe(SO_4)₂, NaFe_{0.8}Cr_{0.2}(SO_4)₂ and NaCr(SO_4)₂ are presented in Fig. 2. It can be noticed that the synthesized materials are crystalline, and the absence of any impurity peak (s) confirm the high purity of the developed materials.

Fig. 3 Final observed, calculated, and difference plots for PXRD (Cu-K α radiation) Rietveld refinement of NaFe_{0.8}Cr_{0.2}(SO₄)₂. [$R_p=0.040$, $R_{wp}=0.052$, $R_{exp}=0.022$].

The XRD data was used to calculate the crystallite size (L) using the well-known Scherrer equation. The calculated crystallite size for the developed NaFe(SO₄)₂, NaFe_{0.8}Cr_{0.2}(SO₄)₂ and NaCr(SO₄)₂ is presented in Table 1.

In order to have more insight of the structural details of the synthesized phases, Rietveld refinement was carried out. Our analysis confirms that $NaFe_xCr_{1-X}(SO_4)_2$ ($X=0,\ 0.8$ and 1.0) adopts a monoclinic crystal structure. As an example, Fig. 3 shows a Rietveld refinement of pristine $NaFe_xCr_{1-X}(SO_4)_2$ where (X=0.8) which shows good agreement between the experimental and calculated patterns.

The refined lattice parameters and other crystallographic information of $NaFe_{0.8}Cr_{0.2}(SO_4)_2$ is presented in Table 2. Moreover, atomic coordinates and isotropic displacement parameters for $NaFe_{0.8}Cr_{0.2}(SO_4)_2$ are also tabulated in Table 3.

The crystal structure for NaFe $_{0.8}$ Cr $_{0.2}$ (SO $_4$) $_2$ is shown in Fig. 4. As can be seen in this structure, the sodium (Na), iron (Fe) and chromium (Cr) ions occupy the octahedral sites in the a-b plane which are bridged together by (SO $_4$) polyanions and creates an interplanar space for 2D Na $^+$ diffusion.

Fig. 5(a–c) shows the morphology of NaFe(SO₄)₂, NaCr(SO₄)₂ and NaFe_{0.8}Cr_{0.2}(SO₄)₂ respectively. It can be clearly seen that the synthesized materials have irregular particle morphology containing primary particle size between 100–200 nm. The particle agglomeration can also be clearly noticed in NaCr(SO₄)₂ and NaFe_{0.8}Cr_{0.2}(SO₄)₂. Fig. 5(d–f) shows the elemental mapping for NaFe_{0.8}Cr_{0.2}(SO₄)₂. It can be clearly seen from

Fig. 5(e and f) that iron and chromium are homogeneously distributed throughout the synthesized materials.

To investigate the thermal stability of NaFe(SO₄)₂, NaFe_{0.8}-Cr_{0,2}(SO₄)₂ and NaCr(SO₄)₂, thermo-gravimetric analysis (TGA) was performed from room temperature to 500 °C in N₂ atmosphere (Fig. 6). The NaFe(SO₄)₂ and NaCr(SO₄)₂ retains about 98.58 and 97.98% of their original weights up to 500 °C respectively. On the other hand, NaFe_{0.8}Cr_{0.2}(SO₄)₂ retains around 99.21% of its original weight. The results clearly indicate that the NaFe(SO₄)₂ and NaCr(SO₄)₂ materials have inferior thermal stability as compared to NaFe_{0.8}Cr_{0.2}(SO₄)₂. The inferior thermal stability of NaFe(SO₄)₂ and NaCr(SO₄)₂ as compared to $NaFe_{0.8}Cr_{0.2}(SO_4)_2$ indicates their inferior structural stability with increasing temperature. Furthermore, small substitution of iron with chromium to form NaFe_{0.8}Cr_{0.2}(SO₄)₂ improves the thermal stability of the material as indicated by weight loss (99.21%). The better thermal stability of chromium doped NaFe_{0.8}Cr_{0.2}(SO₄)₂ may be attributed to stronger bonding between iron (Fe) and chromium (Cr) in the crystal structure. It has been reported earlier that chromium doping enhances the thermal stability of the materials which is due to the high excess stabilization energy of Cr³⁺ in the structure.²⁶⁻²⁸ The stabilized structure therefore, is also expected to improve the electrochemical stability of the material specially at higher temperature.

Fig. 7 shows the FTIR spectra of NaFe(SO_4)₂, NaFe_{0.8}- $Cr_{0.2}(SO_4)_2$ and NaCr(SO_4)₂ recorded between 2500 and

 $500~{\rm cm}^{-1}$. Four main internal modes are observed, which can be described as (i) the symmetric stretching mode ν_1 , (ii) the symmetric bending mode ν_2 , (iii) the asymmetric stretching mode ν_3 , and (iv) the asymmetric bending mode ν_4 . As displayed in Fig. 7 the split of asymmetric stretching (ν_3 : 997 cm⁻¹) and bending (ν_4 : 688 cm⁻¹) modes at a low wavenumber can be ascribed to the peaks for the sulfate group which confirms the formation of sulfate-based materials. These findings are consistent with previous studies. $^{29-31}$

To confirm the electrochemical activity of NaFe(SO₄)₂, NaFe_{0.8}Cr_{0.2}(SO₄)₂ and NaCr(SO₄)₂, differential capacity νs . voltage was plotted as shown in Fig. 8. It can be clearly seen from that NaFe(SO₄)₂ shows a peak at around 3.38 and 3.124 V

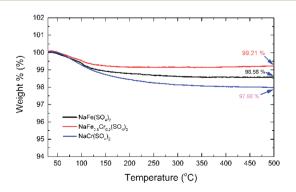

Fig. 6 TGA data for NaFe(SO₄)₂, NaFe_{0.8}Cr_{0.2}(SO₄)₂ and NaCr(SO₄)₂.

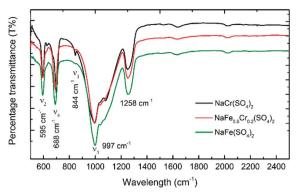

Fig. 7 FTIR spectra for NaFe(SO_4)₂, NaFe_{0.8}Cr_{0.2}(SO_4)₂ and NaCr(SO_4)₂ for the range 500–2500 cm⁻¹.

during oxidation and reduction respectively which corresponds to active $\mathrm{Fe^{2^+}/Fe^{3^+}}$ redox couple. On the other hand, $\mathrm{NaFe_{0.8^-}Cr_{0.2}(SO_4)_2}$ shows peaks at around 3.169 and 3.005 V during oxidation and reduction which also corresponds to $\mathrm{Fe^{2^+}/Fe^{3^+}}$ redox active couple. $\mathrm{NaFe_{0.8}Cr_{0.2}(SO_4)_2}$ demonstrates lesser polarization during charging and discharging whereas $\mathrm{NaFe(SO_4)_2}$ experiences more polarization as evident in $\mathrm{d}Q/\mathrm{d}V$ curves in Fig. 8. It can be noticed that the substitution of iron with chromium reduces the redox potential of $\mathrm{Fe^{2^+}/Fe^{3^+}}$ which may be attributed to multicomponent effect as reported previously. Finally, $\mathrm{NaCr(SO_4)_2}$ shows no oxidation and reduction peaks which clearly indicated the inactive behaviour of $\mathrm{Cr^{2^+}/Cr^{3^+}}$ redox couple in $\mathrm{NaFe_xCr_{1-X}(SO_4)_2}$ (X=0,0.8).

Fig. 9(a-d) shows the electrochemical analysis of NaFe(SO₄)₂ and NaFe_{0.8}Cr_{0.2}(SO₄)₂ under different C-rates. It is pertinent to

Paper

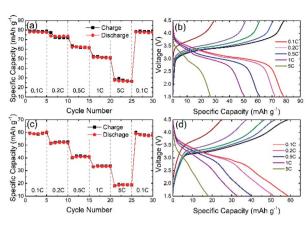

Fig. 9 Rate capability data, and galvanostatic charge–discharge curves at different C-rates for (a and b) NaFe(SO_4)₂, (c and d) NaFe_{0.8}Cr_{0.2}(SO_4)₂.

mention Cr^{2+}/Cr^{3+} redox couple is inactive and thus $NaCr(SO_4)_2$ has not included in the further electrochemical discussion. Fig. 9(a) shows the rate capability data for $NaFe(SO_4)_2$ at different C-rates. The initial discharge capacity at 0.1C is around 78 mA h g⁻¹ which gradually decreases with increasing C-rate *i.e.* the discharge capacity at 1C is 50 mA h g⁻¹ which reduces to 24 mA h g⁻¹ and at 5C. Fig. 9(b) shows the galvanostatic charge/discharge curves for $NaFe(SO_4)_2$ which shows a slanting discharge plateau corresponding to Fe^{2+}/Fe^{3+} redox couple. It can be noticed that intercalation/de-intercalation of sodium into/from the host structure takes place at about 3.2 V due to active Fe^{2+}/Fe^{3+} redox couple which is consistent with dQ/dV analysis shown in Fig. 8.

Fig. 9(c) shows the rate capability data for NaFe_{0.8}Cr_{0.2}(SO₄)₂ at different C-rates. As compared with NaFe(SO₄)₂ the discharge capacity delivered by NaFe_{0.8}Cr_{0.2}(SO₄)₂ is inferior due to the presence of inactive Cr²⁺/Cr³⁺ redox couple as indicated in dQ/ dV analysis. With the addition of chromium, the amount of active iron decrease, therefore, the discharge capacity decreases. It can be noticed that the discharge capacity delivered by NaFe_{0.8}Cr_{0.2}(SO₄)₂ at 0.1C is around 60 mA h g⁻¹ and it also decreases with increasing C-rate similar to NaFe(SO₄)₂ i.e. the capacity at 1C and 5C are around 30 and 15 mA h g⁻¹ respectively. Fig. 9(d) shows the galvanostatic charge/discharge curves for NaFe_{0.8}Cr_{0.2}(SO₄)₂ at different C-rates. The shape of the discharge curves for NaFe_{0.8}Cr_{0.2}(SO₄)₂ is slightly different as compared NaFe(SO₄)₂ which is mainly due to inactive chromium. The average voltage plateau due to active Fe²⁺/Fe³⁺ redox couple is comparatively lower as compared to NaFe(SO₄)₂ which is consistent with our dQ/dV results and may be attributed to multicomponent transition metals effect.29-31 We believe that suitable carbon coating technique to deposit a thin conductive carbon layer on NaCr(SO₄)₂ and NaFe_{0.8}Cr_{0.2}(SO₄)₂ may result in active Cr2+/Cr3+ redox couple leading to better energy storage performance.

To further investigate the activity of the redox couples in $NaFe(SO_4)_2$ and $NaFe_{0.8}Cr_{0.2}(SO_4)_2$, X-ray photoelectron spectroscopy (XPS) was carried out. Fig. 10(a and b) reveals that the Fe is present as Fe^{3+} (binding energy around 725.06 and 712.39

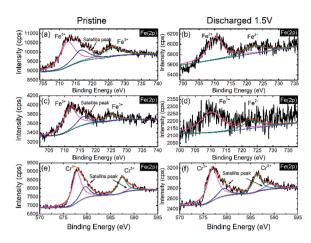

Fig. 10 XPS spectra for Fe in NaFe(SO₄)₂ (a) as prepared electrode, (b) discharged to 1.5 V, Fe in NaFe_{0.8}Cr_{0.2}(SO₄)₂ (c) as prepared electrode, (d) discharged to 1.5 V and Cr in NaFe_{0.8}Cr_{0.2}(SO₄)₂ (e) as prepared electrode, (f) discharged to 1.5 V.

eV) in the as-prepared electrode (before discharge) in NaFe(SO₄)₂, whereas it is reduced to Fe²⁺ (binding energy around 723.5 and 710.3 eV) after the cell is discharged to 1.5 V. The results for Fe in NaFe_{0.8}Cr_{0.2}(SO₄)₂ are similar to NaFe(SO₄)₂ as shown in Fig. 10(c and d). Furthermore, the oxidation state for Cr in NaFe_{0.8}Cr_{0.2}(SO₄)₂ is Cr³⁺ (binding energy around 577.73 and 587.48 eV) in the as-prepared electrode (before discharge) which is not changed after discharging to 1.5 V which clearly shows that Cr³⁺/Cr²⁺ redox couple is inactive and is consistent with the dQ/dV curves (Fig. 8) and charge discharged curves as shown in Fig. 9(b and d).

Interestingly, the slanting voltage plateau in the charge/ discharge curves of NaFe(SO₄)₂ and NaFe_{0.8}Cr_{0.2}(SO₄)₂ indicates the intercalation/de-intercalation of sodium in these materials through a single-phase reaction as reported in previous studies for another cathode materials.24 To confirm the interaction/de-intercalation mechanism of sodium into/from NaFe(SO₄)₂ and NaFe_{0.8}Cr_{0.2}(SO₄)₂ during charging and discharging, the ex situ XRD was employed. For this purpose, the cells were charged/discharged at different cut-off voltages, immediately disassembled in a glove box, washed and dried. Finally, XRD spectra were recorded to study the structural variations during intercalation/de-intercalation of sodium into/ from the host structure. Fig. 11(a and b) shows the ex situ XRD data for NaFe(SO₄)₂ and NaFe_{0.8}Cr_{0.2}(SO₄)₂ respectively. It can be seen from that the XRD patterns that discharging the $NaFe(SO_4)_2$ and $NaFe_{0.8}Cr_{0.2}(SO_4)_2$ to 1.5 V results in shifting of the XRD peaks to lower 2θ values which is due to the expansion of the unit cell due to intercalation of sodium into the host lattice. Furthermore, later charging the cells to 3.0 V and 4.5 V, shifts the XRD peaks to higher 2θ values which may be ascribed to the contraction of the unit cell due to de-intercalation of sodium from the host lattice. It is important to notice that there is only peak shifting during intercalation/de-intercalation and no new peak is generated which reflects the property of singlephase reaction. These results are consistent with the galvanostatic charge/discharge curves with slanting plateau which is

associated with the single-phase mode of intercalation/deintercalation in cathode materials.

Fig. 12 shows the cycling performance of NaFe(SO₄)₂ and NaFe_{0.8}Cr_{0.2}(SO₄)₂ at 0.1C. The initial discharge capacity for NaFe(SO₄)₂ is around 80 mA h g⁻¹ whereas for NaFe_{0.8}Cr_{0.2}(SO₄)₂ it is around 60 mA h g^{-1} . After cycling for 30 cycles, the capacity for NaFe(SO₄)₂ and NaFe_{0.8}Cr_{0.2}(SO₄)₂ is around 73 mA h g^{-1} and 59 mA h g⁻¹ respectively. It is noticed that NaFe(SO_4)₂ shows slow capacity decay with successive cycling. Inset in Fig. 12 shows the capacity retention of NaFe(SO₄)₂ and NaFe_{0.8}Cr_{0.2}(SO₄)₂ after 30 cycles. NaFe(SO₄)₂ and NaFe_{0.8}Cr_{0.2}(SO₄)₂ retains 92.8% and 100% of its initial capacity after 30 cycles.

Conclusions

Phase pure NaFe_xCr_{1-X}(SO₄)₂ cathode materials (where X = 0, 0.8, 1) were synthesized through a sol-gel process and their structural, thermal and electrochemical properties are evaluated. The structural analysis indicates that NaFe_xCr_{1-x}(SO₄)₂ (X = 0, 0.8 and 1.0) adopts a monoclinic crystal structure. It is noticed that NaFe_{0.8}Cr_{0.2}(SO₄)₂ demonstrates better thermal properties as compared to NaCr(SO₄)₂ and NaFe(SO₄)₂. However, substitution of iron (Fe) with chromium (Cr) leads to inferior electrochemical performance which can be essentially ascribed to inactive Cr2+/Cr3+ redox couple. The ex situ XRD shows that the intercalation/de-intercalation mechanism in NaFe(SO₄)₂ and NaFe_{0.8}Cr_{0.2}(SO₄)₂ is governed by single-phase
