The influence of molecular structure on collision radius for optical sensing of molecular oxygen based on cyclometalated Ir(III) complexes†

Ling Di,^{‡a} Yang Xing,^{‡*a} Xiaoning Wang,^a Daoyuan Zheng,^b Yang Yang^{‡b} and Fayun Li^{*a}

Three triphenylamine (TPA) substituted cyclometalated Ir(III) complexes IrA1, IrA2, and IrA3 based on Ir(ppy)₃ were synthesized and applied as phosphorescent probes for the monitoring of molecular oxygen. The phosphorescence intensity of all the Ir(III) complexes in tetrahydrofuran (THF) was gradually quenched with an increase of oxygen concentration. The increase of TPA substituents on the *meta*-position of 2-phenylpyridine (IrA1–IrA3) gradually improved the oxygen sensitivity of cyclometalated Ir(III) complexes. IrA3 showed the highest oxygen sensitivity in THF with a K_{SV}^{app} of 204.8 bar^{−1} and a limit of detection (LOD) of 0.27 mbar. The relationship between molecular structure and the collision radii (σ) of all the Ir(III) complexes has been investigated on the basis of the Demas model and the fundamental expression of luminescence quenching systems by oxygen. The ratio of collision radii are $\sigma_{IrA1}/\sigma_{Ir(ppy)_3} = 1.27 \pm 0.05$, $\sigma_{IrA2}/\sigma_{Ir(ppy)_3} = 1.72 \pm 0.10$, and $\sigma_{IrA3}/\sigma_{Ir(ppy)_3} = 2.13 \pm 0.07$, respectively. The introduction and increase of TPA substituents can obviously increase the collision radii of cyclometalated Ir(III) complexes which leading to potential oxygen sensitivity. And the incremental effect of collision radii caused by the introduction of TPA substituents resulted in outstanding oxygen sensitivity of IrA3. The results demonstrate for the first time evidence between molecular structure and oxygen sensitivity of the emitters for optical sensing.

1. Introduction

Optical sensors have attracted a great deal of interest for oxygen quantification due to the advantages of excellent reversibility, quick response, minimal invasiveness and suitability for monitoring of oxygen in gaseous condition and in solution (dissolved oxygen).^{1–4} Various formats of optical oxygen sensors have been developed including fibre-optic sensors, micro- or nanoparticles, paints and so on.^{5–9} Optical oxygen sensors depended on the dynamic (diffusion-controlled) quenching of emitters by molecular oxygen which is characterized by the Stern–Volmer equation (eqn (1))¹⁰

$$\frac{I_0}{I} = \frac{\tau_0}{\tau} = 1 + k_q \tau_0 [O_2] \quad (1)$$

where I and τ are the intensity and decay time of the emitter respectively. I_0 and τ_0 are the corresponding values in the

absence of oxygen. k_q means bimolecular quenching constant and $[O_2]$ expresses the molar concentration of oxygen. I_0/I (or τ_0/τ) versus $[O_2]$ are linear with slopes of $k_q \tau_0$. In principle, oxygen sensitivity is roughly in proportion to phosphorescent decay time of the emitter.^{11–14} State of the art optical oxygen sensors are mainly made up of phosphorescent iridium, platinum complexes, BF₂, and aluminum chelates, which possess decay time varying in long range of microseconds to milliseconds.^{15–19}

To prevent potential interference and loss of emitters, polymer matrices are often used as permeation-selective barrier.^{20–24} In eqn (2), the oxygen concentration in the polymer matrix is proportional to the oxygen partial pressure (p_{O_2}) just above the film. And the proportionality constant S_{O_2} is the oxygen solubility in organic solvents and polymer matrices defined by Henry's law.²⁵

$$[O_2] = S_{O_2} p_{O_2} \quad (2)$$

Because quenching of phosphorescence is caused by diffusion between emitters and molecular oxygen, the bimolecular quenching constant k_q by the expression (eqn (3))²⁶

$$k_q = \frac{4\pi N_A}{1000} \sigma \alpha D_{O_2} \quad (3)$$

‡ These authors contributed to this work equally.

D_{O_2} is the diffusion coefficient of oxygen in solvents or matrices, and N_A is Avogadro's constant. α represents the probability that a collision leads to quenching. Many authors set α equal to unity for phosphorescence quenching by oxygen in analyzing data.^{27–31} σ is the collision radius of an emitter molecule to molecular oxygen. Upon substitution of eqn (2) and (3) into (1), the fundamental expression (eqn (4)) governing luminescence quenching by oxygen for systems in equilibrium with oxygen was obtained.²⁶

$$\frac{I_0}{I} = \frac{\tau_0}{\tau} = 1 + \frac{4\pi\alpha N_A}{1000} (D_{O_2} S_{O_2}) (\sigma \tau_0) p_{O_2} \quad (4)$$

On one hand, oxygen sensitivity could be effectively enhanced by using of high oxygen permeable matrix. The extent of quenching markedly depends on the oxygen permeability (P_{O_2}) of the matrix, where P_{O_2} is defined as the product of D_{O_2} and S_{O_2} ($P_{O_2} = D_{O_2} S_{O_2}$). Much work so far has focused on the modification of the matrices with fluorinated substituents, *etc.*^{32–35} On the other hand, decay time (τ_0) of the emitters also determined oxygen sensitivity of the sensors. Considerable research efforts have been devoted to the design and synthesis of emitters with long triplet decay time.^{3,11,36,37} Borisov and co-workers reported an aluminium chelate Al(HBANPF)₃ with ultra-long decaying phosphorescence (350 ms). Al(HBANPF)₃ which were immobilized in perfluorinated polymers can monitor oxygen in nearly anoxic system.³ Zhao *et al.* investigated the oxygen sensitivity of two dual-emissive Pt(II) complexes Pt-1 and Pt-2. And Pt-2 with long phosphorescent decay time (3.75 μ s) exhibited higher oxygen sensitivity (136.0 bar^{−1}) compared with short-decay Pt-1 (1.53 μ s, 45.1 bar^{−1}).¹¹ Besides P_{O_2} and τ_0 , the collision radius (σ) of the emitter is the third factor to oxygen sensitivity of emitters which was often ignored by researchers. In some cases, oxygen sensitivity and decay time of emitters are not proportional in the same microenvironment (emitters were immobilized in the same matrix with the same preparation method).^{7,10,22,36–43} For instance, neutral blue emitting cyclometalated Ir(III) complexes Ir-1 and Ir-2 were immobilized in a nanostructured aluminum oxide–hydroxide matrix named AP200/19. Ir-2 with long

phosphorescent decay time showed lower oxygen sensitivity compared to short-decay Ir-1 (Fig. 1).⁴⁰ Phosphorescent decay time of Cu(I) complex Cu-2 is 17-fold longer than Cu-1, however the oxygen sensitivity of Cu-2 is 72% of Cu-1 (Fig. 1).⁴⁴ Obviously, changes of molecular structure of the emitter lead to the changing of the collision radius, and then affect oxygen sensitivity. For quantification of low concentrations or low partial pressures of oxygen, researchers would like to design phosphorescent emitters with long decay time and then immobilized them in the matrices with extremely high oxygen permeability. To the best of our knowledge, no systematic study concerning how change of molecular structure affect the collision radius (σ) of a phosphorescent emitter for optical oxygen sensing.

Triphenylamine (TPA) substituent is an important structural motif in numerous dye-sensitized solar cells (DSSCs) and organic electroluminescence materials because of features, such as non-co-planarity of the three phenyl substituents, strong electron-donating nature and high light-to-electrical energy.^{45,46} Herein, we report a systematic investigation of the

relationship between the molecular structure and the collision radius (σ) of the emitter by modification of cyclometalated Ir(III) complexes Ir(ppy)₃ with incremental introduction of TPA substituents. Chemical structures of cyclometalated Ir(III) complexes IrA1, IrA2, IrA3 and Ir(ppy)₃ are shown in Scheme 1.

2. Result and discussion

2.1. Photophysical and electrochemical property

The photophysical properties of IrA1–IrA3 and Ir(ppy)₃ are exhibited Table 1. The absorptions of 250–375 nm which belong to π – π^* transitions in intraligands enhanced with the incremental introduction of TPA substituents on *meta*-position of 2-phenylpyridine ligands (Fig. 2). The phenomenon also caused the increase of phosphorescence quantum efficiency of Ir(ppy)₃ (0.40), IrA1 (0.48), IrA2 (0.49), and IrA3 (0.53) (Table 1). The transient phosphorescence decay for each Ir(III) complex in THF was mono-exponential, and the lifetimes ranged from 2.38 μ s to 2.93 μ s. Compared to Ir(ppy)₃ (2.38 μ s), phosphorescent lifetime of IrA1 (2.93 μ s) became longer with introducing a TPA substituent on 2-phenylpyridine. Notably, the incremental introduction of TPA substituents on 2-phenylpyridines of Ir(ppy)₃ gradually shortened the lifetimes of cyclometalated Ir(III) complexes. Phosphorescent lifetimes of all the Ir(III) complexes are in the sequence of IrA1 > IrA2 > IrA3 > Ir(ppy)₃ (Fig. S1, see ESI[†]). The emission maxima for all the Ir(III) complexes are in region from 511 to 522 nm. Based on Ir(ppy)₃, the emission maxima of IrA1–IrA3 shifts to a longer wavelength

when increasing TPA substituents at the *meta*-position on benzene ring of 2-phenylpyridine ligands. The change in emission color of all the Ir(III) complexes were quantified with CIE coordinates of Ir(ppy)₃ (0.2750, 0.6268), IrA1 (0.2977, 0.6354), IrA2 (0.3184, 0.6228), and IrA3 (0.3164, 0.6341) in Fig. S2 (see ESI[†]). The electrochemical properties of IrA1–IrA3 and Ir(ppy)₃ were examined using cyclic voltammetry (Fig. S3, see ESI[†]). All the cyclometalated Ir(III) complexes showed reversible oxidation waves. The oxidation potentials of IrA1–IrA3 and Ir(ppy)₃ are 0.78 V, 0.77 V, 0.78 V, and 0.84 V, respectively, which reflected the donor character of TPA groups. The frontier orbital energy levels of all the Ir(III) complexes are given in Table S1 (see ESI[†]).

2.2. Theoretical calculations

Density functional theory (DFT) calculations were performed in order to estimate the ground-state energy levels and electron density distributions of the orbitals of IrA1–IrA3 and Ir(ppy)₃.⁴⁷ And the ground-state geometry of were optimized under the polarizable continuum model (PCM, solvent = THF) of the self-consistent reaction field (SCRf). The HOMO and LUMO iso-surfaces displayed in Fig. 3 have π symmetry with opposite phases above and below the molecular plane. The LUMOs of IrA1–IrA3 and Ir(ppy)₃ consist of a mixture of 2-phenylpyridine moieties. The HOMO of Ir(ppy)₃ is predominantly distributed on the benzene rings of 2-phenylpyridine ligands and Pt atom. The TPA moieties, benzene rings of 2-phenylpyridine ligands and Pt atoms contribute the HOMOs of IrA1–IrA3. The introduction of a TPA substituent on 2-phenylpyridine caused the delocalization of electron from 2-phenylpyridine moieties to the TPA moiety with energy rise (0.29 eV) of HOMO of IrA1. While the incremental introduction of TPA substituents on 2-phenylpyridines have little effect on the HOMOs of IrA2 and IrA3 (Fig. 3).

The low-lying excited states of the singlet (S_1) and the triplet (T_1) of IrA1–IrA3 and Ir(ppy)₃ were also studied with the time-dependent DFT calculations under PCM model (solvent = THF) based on the optimized ground state geometry (Table 2).⁴⁷ The calculated S_1 to T_1 energy gaps of IrA1–IrA3 and Ir(ppy)₃ are 0.33 eV, 0.31 eV, 0.30 eV, and 0.29 eV, respectively. The orbitals are involved in HOMO–3, HOMO–2, HOMO–1, HOMO, LUMO, and LUMO+1. The S_1 and T_1 states of all the Ir(III) complexes were mainly assigned as HOMO to LUMO of electron transition. Similar to Ir(ppy)₃, the S_1 state and T_1 state of IrA3

were rendered with considerable nature of IL, mixed with MLCT character. The S₁ state and T₁ state of IrA1 were rendered with nature of LLCT, MLCT character. And the S₁ state and T₁ state of IrA2 were rendered with nature of IL, LLCT, mixed with MLCT character (Table 2 and Fig. S4 see ESI†).

2.3. Oxygen sensing

Purified tetrahydrofuran (THF) was selected as dispersion phase for the bimolecular quenching process (Fig. 4). The emission of all the Ir(III) complexes obviously weakened with the increase of

oxygen concentration. Above 83% of original intensity was quenched with 6.8% oxygen in the air volume. Notably, the emission of IrA3 was almost completely quenched (above 90% of original intensity) at the oxygen concentration of 6.8% which showed high oxygen sensitivity.

Demas *et al.* have investigated the quenching mechanism of oxygen of several emitters in a lot of polymer matrices.^{48,49} The results showed that heterogeneous microenvironment exists in the emitter-contained matrix. The Demas' model⁴⁸ was introduced to fit the Stern–Volmer plots (SVPs) of all the Ir(III) complexes in THF (Fig. 4) which reads as follows in eqn (5)

Table 2 Electronic excitation energies, oscillator strengths (*f*), configuration–interaction coefficients (CI), and orbital transition contribution percentages (Co) of the low-lying electronically excited states of IrA1–IrA3 and Ir(ppy)₃

^a Only the S₁ and T₁ states are presented. ^b Oscillator strengths. And the oscillator strengths of the T₁ states are zero because of the neglect of spin–orbit coupling in time-dependent DFT calculations. ^c Only the main configurations are presented. H and L denote HOMO and LUMO, respectively.

^d The configuration–interaction coefficients (CI) are in absolute values. ^e The contribution percentages of orbital transitions. Only the orbital pairs whose Co values above 10% are presented. ^f IL: intraligand, LLCT: ligand-to-ligand charge transfer, MLCT: metal-to-ligand charge transfer.

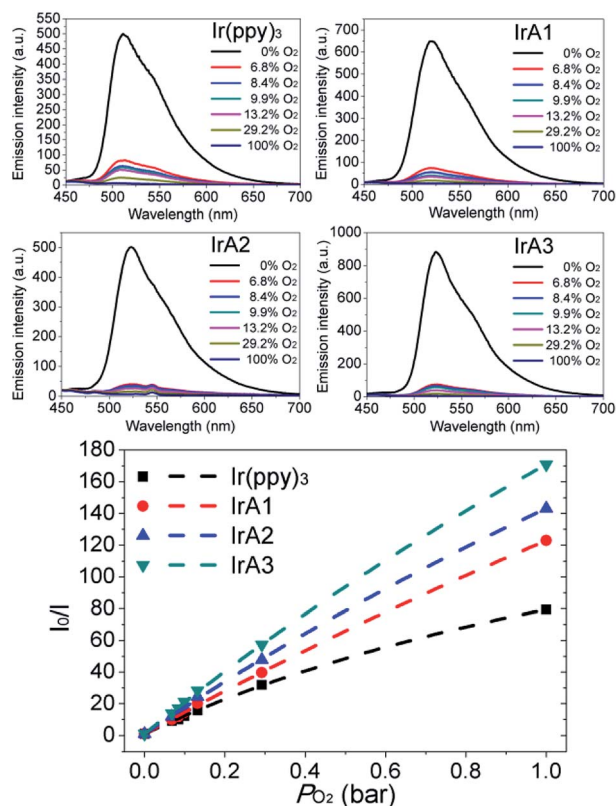

Fig. 4 Dependence of emission spectra and Stern–Volmer plots of all the Ir(III) complexes; 10^{-5} M in THF on oxygen concentration of 0–100%, 25 °C.

$$\frac{I}{I_0} = \frac{\tau}{\tau_0} = \frac{f_1}{1 + K_{SV1}P_{O_2}} + \frac{f_2}{1 + K_{SV2}P_{O_2}} \quad (5)$$

f_1 and f_2 are fractions of two microenvironments of the heterogeneous optical sensing system, respectively, which are defined as $f_1 + f_2$ being 1. f_1 is the quenchable fraction with quenching rate constant K_{SV1} , and f_2 is the fraction which is not quenched at all with quenching rate constant K_{SV2} . Weighted quenching constant K_{SV}^{app} ($K_{SV}^{app} = f_1 \times K_{SV1} + f_2 \times K_{SV2}$) is the guide of oxygen sensitivity of an optical oxygen sensor. The Demas' model is well-suited to describe homogeneity of oxygen sensing system. The Stern–Volmer constants for all the Ir(III) complexes in THF are summarized in Table S2 (see ESI†). The I_0/I_{100} of IrA1–IrA3 and Ir(ppy)₃ are 122.9, 143.2, 170.8, and 79.4. And K_{SV}^{app} are 138.6 bar^{-1} , 171.4 bar^{-1} , 204.8 bar^{-1} , and 119.6 bar^{-1} , respectively. IrA3 showed outstanding oxygen sensitivity in THF. Contrary to the sequence of phosphorescent lifetimes, the oxygen sensitivities are in the following order: IrA3 > IrA2 > IrA1 > Ir(ppy)₃. Compared to Ir(ppy)₃, the introduction of TPA substituents on cyclometalating ligand 2-phenylpyridine improved oxygen sensitivity of cyclometalated Ir(III) complexes. On the other hand, the increase of TPA substituents on *meta*-position of 2-phenylpyridine ligands (IrA1–IrA3) gradually improved the oxygen sensitivity (Fig. 4). Large quenchable fractions (f_1) of IrA1 (0.999), IrA2 (0.998), and IrA3 (0.998) are

higher than Ir(ppy)₃ (0.985) which exhibited remarkable linearity of SVPs (Table S2, see ESI†). With the introduction of TPA substituents at *meta*-position on 2-phenylpyridine ligands, f_1 values were steadily improved which caused more homogeneous microenvironment (high oxygen sensitivity) of cyclometalated Ir(III) complexes. The limit of detection (LOD) of all the cyclometalated Ir(III) complexes in THF was calculated of IrA1 (0.39 mbar), IrA2 (0.30 mbar), IrA3 (0.27 mbar) compared to Ir(ppy)₃ (0.43 mbar) (see ESI†).

From eqn (4), the ratio of collision radii (σ_1/σ_2) of two emitters with different molecular structure under homogeneous microenvironment and uniform oxygen partial pressure is obtained by the expression, reads as (eqn (6))

$$\frac{\sigma_1}{\sigma_2} = \frac{\left[\left(\frac{I_0}{I}\right)_1 - 1\right]\tau_2}{\left[\left(\frac{I_0}{I}\right)_2 - 1\right]\tau_1} \quad (6)$$

The relationship between molecular structure and the collision radius have been investigated by parallelly measuring data of I_0 and I_{100} five times. And results of bimolecular quenching process in THF and phosphorescent decay time of IrA1–IrA3 and Ir(ppy)₃ were employed for analyzing the variation of collision radii (Fig. 5 and Table S3, see ESI†). The ratio of collision radii are $\sigma_{IrA1}/\sigma_{Ir(ppy)_3} = 1.27 \pm 0.05$, $\sigma_{IrA2}/\sigma_{Ir(ppy)_3} = 1.72 \pm 0.10$, and $\sigma_{IrA3}/\sigma_{Ir(ppy)_3} = 2.13 \pm 0.07$, respectively. Comparison with Ir(ppy)₃, the collision radius of IrA1 can be obviously increased with the introduction of a TPA substituent at *meta*-position on benzene ring of 2-phenylpyridine ligand. And compared to IrA1, the progressive increase of TPA substituents on the rest of 2-phenylpyridine ligands strongly increased the collision radius of cyclometalated Ir(III) complexes (IrA2 and IrA3) as well which leading to higher collision probability between cyclometalated Ir(III) complexes and molecular oxygen, and provided potential oxygen sensitivity.

As a practical performance, IrA3 was composited with a thin film of silicon gel supported on a glass slide to construct a simple oxygen sensor. The phosphorescence of IrA3 oxygen sensor was totally quenched in air atmosphere and emitted bright yellow-green light under N₂ stream. The quenching-emission response of IrA3 oxygen sensor is ultrafast and fully reversible that a flame-like light spot can be seen (Fig. 6).

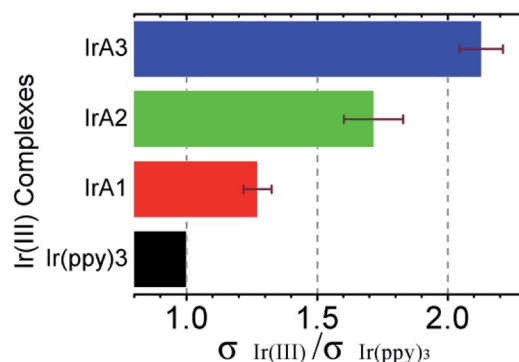

Fig. 5 The variation of collision radii of IrA1–IrA3 via Ir(ppy)₃ for bimolecular quenching process.

Fig. 6 (A) Photographs of a IrA3 oxygen sensor excited at 365 nm under air (B) with a nitrogen stream in copper pipe.

3. Conclusions

In conclusion, three TPA substituted cyclometalated Ir(III) complexes IrA1, IrA2, and IrA3 based on Ir(ppy)₃ were synthesized and applied as phosphorescent probes for analysis of molecular oxygen. The phosphorescent intensity of Ir(III) complexes in THF was drastically changed by the oxygen concentration. IrA3 demonstrated the highest oxygen sensitivity with I_0/I_{100} of 170.8, K_{SV}^{app} of 204.8 bar⁻¹, and LOD of 0.27 mbar. With the incremental introduction of TPA substituents at *meta*-position on 2-phenylpyridine ligands of Ir(ppy)₃, the oxygen sensitivities of IrA1–IrA3 were obviously improved, and the f_1 values were gradually increased which caused more homogeneous oxygen sensing system and high oxygen sensitivity. The relationship between molecular structure and the collision radius of the emitter for optical oxygen sensing have been investigated and quantized through the cooperation of the Demas' model and the fundamental expression of luminescence quenching systems by oxygen. The incremental introduction of TPA substituents could effectively increase the collision radiuses of cyclometalated Ir(III) complexes which leading to more likely collision between the emitter and molecular oxygen, and provided high oxygen sensitivity. This research could potentially be applied as new prospect for molecular structure design of the emitter with high oxygen sensitivity for optical monitoring of molecular oxygen.

4. Experimental

4.1. Materials and methods

Unless otherwise noted, all the cross-coupling reactions for preparing the ligands were carried out in air. 2-Bromopyridine, (3-bromophenyl)boronic acid, (4-(diphenylamino)phenyl)boronic acid, phenylboronic acid, and iridium(III) chloride trihydrate were purchased from Adamas. Other chemicals were purchased from commercial sources and used without further purification. ¹H NMR and ¹³C NMR spectra were recorded on a BRUKER AVANCE III HD 500 MHz spectrophotometer. Mass spectra were recorded with a MALDI micro MX spectrometer. Phosphorescence lifetimes were determined on a Laser Flash Photolysis (LFP) (Dalian Institute of Chemical Physics). Absorption spectra were recorded by Cary series 5000 UV-Vis-NIR spectrometer (Agilent Technologies). Emission spectra

were recorded by Cary Eclipse G9800A fluorescence spectrophotometer (Agilent Technologies). Cyclic voltammograms were recorded on an electrochemical workstation PARSTAT 2273 (Princeton Applied Research) at room temperature.

4.2. Synthesis section

Synthetic procedure of 2-(3-bromophenyl)pyridine. A mixture of 2-bromopyridine (2.0 mmol, 191 μL), 1.5 equiv. of (3-bromophenyl)boronic acid (3.0 mmol, 482 mg), 2 equiv. of K₂CO₃ (4.0 mmol, 548 mg), Pd(OAc)₂ (1.5 mol%, 0.03 mmol, 6.74 mg), ethanol/water (6 mL/2 mL) was stirred at 80 °C in air for indicated time. The reaction mixture was added to brine (15 mL) and extracted four times with ethyl acetate (4 × 15 mL). The solvent was concentrated and the product 2-(3-bromophenyl)pyridine was isolated by short-column chromatography on silica gel (200–300 mesh).

2-(3-Bromophenyl)pyridine.¹² Yield: 53.2%; colorless oil. ¹H NMR (500 MHz, CDCl₃): δ 8.70 (d, 1H), 8.17 (s, 1H), 7.91 (d, 1H), 7.77 (td, 1H), 7.71 (d, 1H), 7.54 (dd, 1H), 7.34 (t, 1H), 7.29–7.25 (m, 1H).

Synthetic procedure of ligand *N,N*-diphenyl-3'-(pyridin-2-yl)-[1,1'-biphenyl]-4-amine (L1). A mixture of 2-(3-bromophenyl)pyridine (0.25 mmol, 58.25 mg), 1.5 equiv. of (4-(diphenylamino)phenyl)boronic acid (0.375 mmol, 108.40 mg), 2 equiv. of K₂CO₃ (0.5 mmol, 69 mg), Pd(OAc)₂ (1.5 mol%, 0.00375 mmol, 0.84 mg), ethanol/water (3 mL/1 mL) was stirred at 80 °C in air for indicated time. The reaction mixture was added to brine (15 mL) and extracted four times with ethyl acetate (4 × 15 mL). The solvent was concentrated and the product L1 was isolated by short-column chromatography on silica gel (200–300 mesh).

L1. Yield: 84.2%; white solid. ¹H NMR (500 MHz, CDCl₃): δ 8.71 (s, 1H), 8.20 (d, 1H), 7.92 (d, 1H), 7.77 (d, 2H), 7.63–7.50 (m, 4H), 7.26 (d, 5H), 7.17–7.11 (m, 6H), 7.07–6.98 (m, 2H). ¹³C NMR (126 MHz, CDCl₃): δ 157.5, 149.7, 147.7, 147.3, 141.2, 139.9, 136.8, 135.0, 129.3, 129.2, 128.0, 127.3, 125.4, 125.4, 124.4, 123.9, 122.9, 122.2, 120.7. HRMS (EI): calc.: 398.1783 [M]⁺. Found: 398.1780 [M]⁺.

Synthetic procedure of IrA1. The cyclometalating ligand 2-phenylpyridine (0.4 mmol, 57 μL) was reacted with 0.6 equiv. IrCl₃·3H₂O (0.24 mmol, 84.5 mg) in a mixture of 2-ethoxyethanol and water (9 mL/3 mL) at 105 °C for 24 h to afford an iridium dimer, which was subsequently reacted with 0.6 equiv. of the cyclometalating ligand L1 (0.24 mmol, 95.5 mg) and 5 equiv. of Na₂CO₃ (2 mmol, 212 mg) in glycerol (10 mL) at 200 °C for 48 h.

IrA1. Yield: 73.6%; yellow acicular microcrystal. ¹H NMR (500 MHz, CDCl₃): δ 7.96 (td, 2H), 7.86 (d, 4H), 7.64 (d, 2H), 7.58–7.54 (m, 2H), 7.51 (dd, 2H), 7.27–7.20 (m, 4H), 7.11 (d, 10H), 6.98 (dd, 3H), 6.85 (dd, 8H). ¹³C NMR (126 MHz, CDCl₃): δ 166.7, 166.6, 161.3, 147.9, 147.1, 147.1, 145.9, 144.3, 143.7, 137.4, 137.1, 135.9, 129.9, 129.2, 127.1, 124.7, 124.0, 123.9, 122.5, 122.1, 121.9, 119.9, 119.8, 118.9, 118.8. HRMS (EI): calc.: 898.2647 [M]⁺. Found: 898.2646 [M]⁺.

Synthetic procedure of IrA2. The cyclometalating ligand L1 (0.4 mmol, 159.2 mg) was reacted with 0.6 equiv. IrCl₃·3H₂O (0.24 mmol, 84.5 mg) in a mixture of 2-ethoxyethanol and water

(9 mL/3 mL) at 105 °C for 24 h to afford an iridium dimer, which was subsequently reacted with 0.6 equiv. of the cyclometalating ligand 2-phenylpyridine (0.24 mmol, 34.2 μ L) and 5 equiv. of Na₂CO₃ (2 mmol, 212 mg) in glycerol (10 mL) at 200 °C for 48 h.

IrA2. Yield: 71.0%; yellow acicular microcrystal. ¹H NMR (500 MHz, CDCl₃) δ 7.96 (t, 4H), 7.85 (d, 4H), 7.61–7.54 (m, 6H), 7.50 (dd, 4H), 7.26–7.20 (m, 8H), 7.10 (d, 12H), 6.98 (dd, 8H), 6.85 (d, 4H). ¹³C NMR (126 MHz, CDCl₃) δ 166.8, 166.7, 148.0, 147.3, 147.2, 146.0, 144.4, 143.8, 137.5, 137.2, 137.0, 136.1, 132.2, 130.0, 129.9, 129.3, 128.6, 127.2, 124.8, 124.1, 122.6, 122.2, 120.1, 119.9, 118.9. HRMS (EI): calc.: 1141.3695 [M]⁺. Found: 1141.3692 [M]⁺.

Synthetic procedure of IrA3. The cyclometalating ligand L1 (0.4 mmol, 159.2 mg) was reacted with 0.6 equiv. IrCl₃·3H₂O (0.24 mmol, 84.5 mg) in a mixture of 2-ethoxyethanol and water (9 mL/3 mL) at 105 °C for 24 h to afford an iridium dimer, which was subsequently reacted with 0.6 equiv. of the cyclometalating ligand L1 (0.24 mmol, 95.5 mg) and 5 equiv. of Na₂CO₃ (2 mmol, 212 mg) in glycerol (10 mL) at 200 °C for 48 h.

IrA3. Yield: 68.7%; yellow acicular microcrystal. ¹H NMR (500 MHz, CDCl₃) δ 7.98 (d, 3H), 7.87 (s, 3H), 7.61 (dd, 6H), 7.50 (d, 6H), 7.27–7.21 (m, 9H), 7.11 (d, 24H), 6.98 (dd, 7.4 Hz, 9H), 6.92–6.88 (m, 3H). ¹³C NMR (126 MHz, CDCl₃) δ 166.8, 166.7, 148.0, 147.3, 146.0, 144.4, 137.5, 136.9, 136.2, 129.3, 128.7, 128.6, 127.1, 124.7, 124.16, 124.1, 122.5, 122.2, 119.0. HRMS (EI): calc.: 1384.4743 [M]⁺. Found: 1384.4743 [M]⁺.

4.3. Oxygen sensing

The specific concentrations of oxygen in nitrogen at atmospheric pressure (from 0–100% in volume fraction) were generated with two tube flowmeter. The volumetric flow rate was monitored by bubble flowmeter.¹⁰

4.4. IrA3 oxygen sensor

IrA3 was immobilized in a silicon gel plate (the layer thickness of silicon gel is 0.2 \pm 0.03 mm; the granularity of silicon gel is 8 \pm 2 μ m) using thin-layer chromatography technic with IrA3–THF eluent solution (0.05 mg mL^{−1}). The silicon gel oxygen sensor was dried for 4 h to remove THF before oxygen sensing tests.

Conflicts of interest

There are no conflicts to declare.
