A facile method to synthesize CoV₂O₆ as a high-performance supercapacitor cathode†

Xinrui He,‡ Jing Jiang,‡ Hanqing Tian, Yi Niu, Zhipeng Li, Yalin Hu, Jiahao Fan and Chao Wang (1)*

Transition metal oxides can easily lose electrons and thus possess multiple accessible valences. Especially, if two different transition metals are combined, better capacity and cycling stability are achieved. In this study, a binary transition metal oxide, CoV_2O_6 , was synthesized *via* a facile co-precipitation process for use as a supercapacitor cathode; the as-synthesized CoV_2O_6 exhibited high-capacity (306.6 F g⁻¹, 1 A g⁻¹ and 219.2 F g⁻¹, 20 A g⁻¹) and stable cycling stability, retaining 83.3% of its initial specific capacitance after 20 000 cycles. We believe that this facile synthesis process presents an effective method and a new opportunity for promoting the application of electrode materials based on binary transition metal oxides in supercapacitors.

Introduction

The development of supercapacitor materials with high capacitance and cycling stability is of significant importance for next generation energy storage devices.1 The type of electrode materials has been considered as a critical factor affecting the electrochemical performance of the supercapacitors; therefore, there is an urgent need for researchers to develop new electrode materials that are efficient, clean and sustainable.2-4 To date, various materials, such as carbon-based materials,5-11 conducting polymers12-14 and transition-metal oxides,15-18 have been employed as electrodes for supercapacitors. Among these materials, transition metal oxides are considered promising due to their unfilled valence d orbitals (based on the 18 electron rules), which can easily lose electrons and thus achieve multiple accessible valence states to enable a variety of reversible Faraday redox reactions. Furthermore, when two different transition metals are combined, the resulting material exhibits complex chemical compositions and synergistic effect and has high electrochemical activity.

Recently, significant efforts have been made to improve the electrochemical performance of electrode materials by synthesizing transition metal oxides. Tarasankar Pal and his coworkers have described an asymmetric supercapacitor, Ni₃-V₂O₈@MWCNT, νia a laboratory-developed modified hydrothermal technique. Ling-Bin Kong and his co-workers have synthesized a hybrid Ni₃V₂O₈/Co₃V₂O₈ nanocomposite by

State Key Laboratory of Electronic Thin Films and Integrated Devices, School of Electronic Science and Engineering, University of Electronic Science and Technology of China, Chengdu 611731, China. E-mail: cwang@uestc.edu.cn

growing $\text{Co}_3\text{V}_2\text{O}_8$ nanoparticles on the surface of $\text{Ni}_3\text{V}_2\text{O}_8$ nanoflakes. H. Chai and his co-workers²¹ have reported the quasi-cuboidal CoV_2O_6 via a microwave-assisted method. Unfortunately, these binary transition metal oxides are either limited by their low electrochemical properties or by technical issues. The complicated synthetic process limits the application of supercapacitors in practical work, and it is necessary to propose a facile and efficient strategy to shorten the material preparation cycle for large-scale production.

In this study, we present a facile chemical co-precipitation process for the synthesis of the high-performance binary transition metal oxide CoV_2O_6 . In this process, mild time and energy saving approaches have been developed to achieve the material synthesis. When directly applied as an electrode material, CoV_2O_6 exhibited high-capacities (306.6 F g⁻¹, 1 A g⁻¹; 219.2 F g⁻¹, 20 A g⁻¹) and stable rate capability: after 20 000 cycles, about 83.3% of the capacity was still retained. This strategy opens up a new window for the synthesis of transition metal oxides for application in high-performance supercapacitors.

Experimental

Materials

In this study, we used $CoCl_2 \cdot 6H_2O$ (AR Aladdin Shanghai, China), Na_3VO_4 (AR Aladdin Shanghai, China) and KOH (ChengDu KeLong Glass Co. Ltd. ChengDu, China). All the chemicals were of analytical grade and used without any further purification.

Synthesis of CoV₂O₆

In a typical procedure, 3 mmol CoCl₂·6H₂O was dissolved in 20 mL deionized water under magnetic stirring at 70 °C for a certain period of time. After this, 2 mmol Na₃VO₄ was

[†] Electronic supplementary information (ESI) available. See DOI: 10.1039/c8ra10041a

[‡] These authors contributed equally to this work.

RSC Advances

dissolved in another 20 mL deionized water under magnetic stirring, and then, this solution was added drop-wise to the cobalt chloride solution. The reaction mixture solution was subsequently stirred vigorously for additional 2 h at 70 °C. After the homogeneous solution was cooled down to room temperature, a brown-red powder precipitate was obtained by washing the homogeneous solution several times with deionized water followed by drying at 60 °C for 12 h in a vacuum oven. Finally, the products were annealed in air at 600 °C for 3 h to obtain CoV₂O₆.

Characterization

The crystal structure of the products was characterized by X-ray diffraction (XRD), conducted in the range from 10 to 80° using the DX-2700B (Haoyuan) diffractometer with Cu K α radiation (λ = 1.5406 Å). The morphology and microstructure of the products were analyzed by scanning electron microscopy (FESEM, JSM-7600F) and transmission electron microscopy (TEM, G2-F30). Moreover, the chemical compositions were examined by XPS measurements via ESCALAB 250Xi using Al Kα radiation at 1486.6 eV. The specific surface area and porosity were calculated by the N₂ adsorption-desorption measurement using the Quadrasorb instrument.

Electrochemical measurement

All the electrochemical tests were carried out via an electrochemical workstation (CHI 660E, CHI Instrument Inc., Shanghai) with a three-electrode electrochemical system in a 3 M KOH aqueous solution. The CoV₂O₆/nickel foam was used as the working electrode, and a platinum plate and Hg/HgO served as the counter and reference electrodes, respectively. The working electrode was prepared by mixing CoV2O6, acetylene and poly(vinylidene difluoride) at the mass ratio of 7:2:1 in a N-methyl-2-pyrrolidinone solvent to form a slurry. The slurry was then coated on the one side of the nickel foam (1 cm × 1 cm) current collectors followed by drying in the vacuum oven at 60 °C for 12 h. Finally, the CoV₂O₆/nickel foam was pressed at 10 MPa, and the mass loading was equal to 1.4 mg. Then, cyclic voltammetry (CV) and galvanostatic charge/ discharge (GCD) were performed in the potential window of 0-0.5 V. The specific capacitance was calculated using the following equation:22

$$C = \frac{I\Delta t}{m\Delta V}$$

where C (F g^{-1}) is the specific capacitance, I (A) is the current density, Δt (s) is the discharge time, m (g) is the mass of active electrode materials and ΔV (V) is the potential window. The frequency range of the electrochemical impedance spectroscopy (EIS) measurements was from 10^{-2} to 10^{5} Hz.

Results and discussion

The synthesis process of CoV₂O₆ is presented in Fig. 1. CoV₂O₆ was prepared by a facile chemical co-precipitation process. The structural features of CoV_2O_6 are as follows: it consists of linear

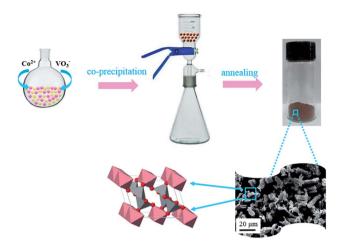

Fig. 1 Schematic of the synthesis of CoV₂O₆. Pink, gray and red represent Co, V, and O, respectively.

chains formed by the Co²⁺ ions in the CoO₆ octahedron as well as zigzag chains formed by the V⁵⁺ ions in VO₅. All the chains are along the b-axis, resulting in a quasi-one-dimensional (1D) structural arrangement (a = 9.256 Å, b = 3.508 Å, c = 6.626 Å,and $\beta = 111.55^{\circ}$ with the space group C2(5)).²³ The chemical reactions can be expressed as follows:

$$\text{Co}^{2+} + 2\text{VO}^{3-} + n\text{H}_2\text{O} \rightarrow \text{CoV}_2\text{O}_6 \cdot n\text{H}_2\text{O}$$
 (1)

$$CoV_2O_6 \cdot nH_2O \rightarrow CoV_2O_6 + nH_2O$$
 (2)

The X-ray diffraction (XRD) patterns of the samples are shown in Fig. 2. CoV₂O₆·4H₂O (PDF#77-0485) was obtained by the chemical co-precipitation process. After the annealing treatment, high-purity monoclinic CoV₂O₆ (PDF#77-1174) was obtained. The annealed samples showed sharp diffraction peaks, which proved the successful synthesis of CoV₂O₆ via the facile chemical co-precipitation process.

Moreover, X-ray photoelectron spectroscopy (XPS) was used to further confirm the chemical compositions of CoV₂O₆. The

Paper

full spectrum of CoV₂O₆ is shown in Fig. S1.† There are two main peaks at 781.47 eV and 797.50 eV in the Co 2p spectrum shown in Fig. S1(b)† due to the spin orbit coupling, corresponding to the hybrid orbitals Co 2p_{3/2} and Co 2p_{1/2}.²⁴ The 5d orbitals of the central ions of transition metals become energy degenerate in the imaginary sphere field when subjected to a negative electric field of the ligand. The energy level splitting produces 16.03 eV splitting energy. In addition, two shake-up satellite peaks are observed at 786.18 eV (suggesting that the Co²⁺ ions are in an octahedral coordination,²⁵ matching with the abovementioned structural features) and 803.61 eV, supporting the existence of Co²⁺. Fig. S1(c)† displays the V 2p spectrum of V 2p_{3/2} (516.94 eV) and V 2p_{1/2} (524.19 eV) with a splitting energy of 7.25 eV, indicating that V5+ also exists. The XPS spectrum of O 1s in Fig. S1(d)† exhibits one typical peak at the binding energy of 530.37 eV assigned to O^{2-} .

It has been reported that the specific surface area of the electrode materials plays a crucial role in their electrochemical properties.26 The results of characterization obtained by the Brunauer-Emmett-Teller (BET) surface analysis are shown in Fig. S2.† Fig. S2(a and b)† display the specific surface areas of $48.819 \text{ m}^2 \text{ g}^{-1}$ for $\text{CoV}_2\text{O}_6 \cdot 4\text{H}_2\text{O}$ and $86.786 \text{ m}^2 \text{ g}^{-1}$ for CoV_2O_6 . After the annealing treatment, higher specific surface area is obtained. The pore size distributions show a uniform pore structure, and the pore size of CoV₂O₆·4H₂O is about 3.6 nm and that of CoV₂O₆ is 2.6 nm on the basis of the Barrett-Joyner-Halenda (BJH) analysis results shown in Fig. S2(c and d).† In general, after the annealing treatment, the pore size and the pore volume of the samples decrease; this leads to an increase in the surface area. A larger surface area provides more active sites for ions to participate in the reaction, and thus, a high electrochemical property is obtained.

The surface morphology of CoV₂O₆ was characterized by scanning electron microscopy and transmission electron microscopy. Fig. 3(a, b) and S3† show the different magnification SEM images of CoV2O6. CoV2O6 reveals a sponge-like morphology with nanoscale voids constructed by interconnected nanoflakes, and the lengths of the nanoflakes are in the range of 1-5 μ m²⁷, which improve the specific surface area and optimize the pore size distribution. Consequently, this provides faster transport channels for ions and electrons in the longitudinal direction; this leads to the internal resistance reduction and electrochemical property increment. Fig. S4† shows an irregular cubic structure with lateral sizes between 1 and 20 µm for CoV2O6·4H2O. CoV2O6·4H2O has a smooth surface; however, it agglomerates severely. Furthermore, the morphology of the electrode after cycling is observed by SEM (Fig. S5†). Although a portion of the active materials has collapsed after cycling, the main sponge-like morphology is still retained, and these structures provide sufficient transport channels for the ions and electrons. The TEM images shown in Fig. 3(c and d) indicate that the lattice fringe spacing is approximately 0.2 nm, corresponding to the lattice plane of (003). As observed from the elemental mapping shown in Fig. 3(e), each element is evenly distributed; the more uniform the distribution of the elements, the higher the purity of the samples. An energy dispersive spectrometer (EDS) was

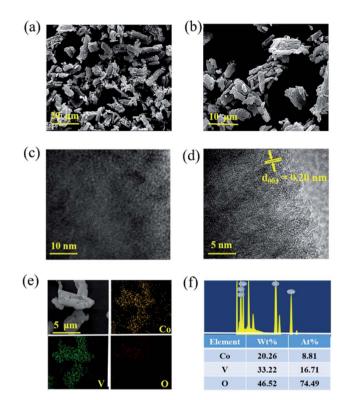

Fig. 3 (a and b) SEM images of CoV_2O_6 , (c and d) TEM images of CoV_2O_6 , (e) SEM image of CoV_2O_6 and its corresponding elemental mapping images: Co, V, and O elements, and (f) the EDS spectrum of CoV_2O_6 .

employed to analyse the types and contents of CoV_2O_6 and $CoV_2O_6 \cdot 4H_2O$. The results are shown in Fig. 3(f) and S6,† confirming the existence of Co, V, and O. Moreover, the atomic ratio of Co/V is about 1:2, which matches well with the chemical formula. To better determine the masses of Co and V, ICP-OES (Inductively coupled plasma optical emission spectrometry) was conducted. The element content of Co and V is 24.6% and 38.1%, respectively. Since cobalt and vanadium are the main components in the sample (more than 10%), the solution needs to be diluted to a large multiple; thus, the result is not the ideal value of 1:2 but is approximately 1:1.5.

Fig. 4(a) reveals the cyclic voltammetry (CV) curves obtained at the scan rates of 10, 20, 30, 40, and 50 mV s⁻¹ in the potential window of 0–0.5 V. The redox peaks can be clearly observed, indicating that pseudocapacitance plays a dominant role. The cyclic voltammetry curves obtained at different scanning speeds show similar shapes. Generally, these peaks correspond to the reversible reaction of $\mathrm{Co^{3+}/Co^{2+}}$ associated with the anions $\mathrm{OH^{-1.18,19,28-31}}$ Based on these findings, the reaction mechanism of $\mathrm{CoV_2O_6}$ can be presented by following equations:

$$Co^{2+} + 2OH^{-} \rightarrow Co(OH)_{2}$$
 (3)

$$Co(OH)_2 + OH^- \rightarrow CoOOH + H_2O + e^-$$
 (4)

As the current density increases, the oxidation product and the reduction product migrate to the anode and the cathode, respectively, which are produced during the electrochemical Open Access Article. Published on 26 March 2019. Downloaded on 7/23/2025 1:30:44 PM.

reaction due to the irreversible reactions and electric polarization.

To further investigate the electrochemical performance of CoV₂O₆, we tested the galvanostatic charge-discharge (GCD) (Fig. 4(b)) in the potential window of 0-0.5 V. The current density is 1, 2, 4, 8, 10, and 20 A g⁻¹ corresponding to 306.6, 280.8, 261.5, 232.0, 220.0, and 219.2 F g⁻¹. A detailed comparison is shown in Table S2.† The electrochemical performances of CoV₂O₆ synthesized by different methods are quite different, which may be related to their different morphologies. These sponge-like CoV₂O₆ have a thinner structure, and they allow more active materials to participate in the Faraday reaction. However, the quasi-cuboidal CoV₂O₆ may lock more active substances in the cubic structure. More surprisingly, when the electrode material is subjected to charge and discharge testing at high current density, CoV₂O₆ also exhibits a high-capacity (219.2 F g⁻¹, 20 A g⁻¹), which is approximately equal to that of the quasi-cuboidal CoV_2O_6 (223 F g^{-1} , 1 A g^{-1}), and a detailed comparison is shown in Table S2.† When the current density increases from 1 to 20 A g⁻¹, the specific capacitance is still retained at 71.49%; thus, this indicates excellent electrochemical performance of the CoV2O6 electrode materials for supercapacitors.

In addition, electrochemical impedance spectroscopy (EIS) was used to understand the conductive and diffusive behaviour³² of CoV₂O₆. The study reveals the EIS in the range from

0.01 Hz to 100 000 Hz with an amplitude of 10 mV. It was carried out before and after continuous charging and discharging for 20 000 cycles, as shown in Fig. 4(c) and S7.† The Nyquist plots show that the $R_{\rm s}$ value of ${\rm CoV_2O_6}$ is 0.47 Ω ; after cycling, it increases to 0.68 Ω . The $R_{\rm ct}$ value before and after cycling are 1.53 Ω and 0.24 Ω , respectively. This small change demonstrates that the electrode material has an excellent electrochemical performance.³³

Note that materials with better cycling stability are more promising in commercial applications. Therefore, CoV_2O_6 was tested *via* 20 000 cycles of continuous charge and discharge at the current density of 4 A g⁻¹. Fig. 4(d) shows that in the first cycle, the specific capacitance of CoV_2O_6 is about approximately 192 F g⁻¹. As the number of cycles increases, the specific capacitance of the electrode shows an upward trend in the first 1200 cycles, then decreases slowly, and after 20 000 cycles, the final retention rate is 83.3%.

Conclusions

In conclusion, we reported a facile chemical co-precipitation process for the synthesis of the binary transition metal oxide CoV_2O_6 . CoV_2O_6 demonstrates typical features as follows: (1) high-capacity of $306.6 \, F \, g^{-1}$ at the current density of $1 \, A \, g^{-1}$, and even at the high current density of $20 \, A \, g^{-1}$, it still achieves $219.2 \, F \, g^{-1}$, (2) stable cycling stability, *i.e.*, 83.3% retention of

Paper

the initial value after 20 000 cycles. Accordingly, the superior performance of the CoV_2O_6 electrode can be attributed to the multiple accessible valence states, which enable fast faradaic reaction. Especially, when two different transition metals are combined, better capacity and cycling stability are achieved. We believe that this study presents an effective method and a new opportunity for promoting the application of electrode materials based on transition metal oxides in supercapacitors.
