## $\beta$ -Ga<sub>2</sub>O<sub>3</sub> nanorod arrays with high light-to-electron conversion for solar-blind deep ultraviolet photodetection

Shunli Wang,<sup>†,a</sup> Kai Chen,<sup>†,a</sup> Hailin Zhao,<sup>a</sup> Chenran He,<sup>a</sup> Chao Wu,<sup>id,a</sup> Daoyou Guo,<sup>id,\*a</sup> Nie Zhao,<sup>c</sup> Goran Ungar,<sup>id,ad</sup> Jingqin Shen,<sup>a</sup> Xulong Chu,<sup>be</sup> Peigang Li<sup>\*b</sup> and Weihua Tang<sup>b</sup>

Vertically aligned nanorod arrays (NRAs), with effective optical coupling with the incident light and rapid electron transport for photogenerated carriers, have attracted much interest for photoelectric devices. Herein, the monoclinic  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs with an average diameter/length of 500 nm/1.287  $\mu$ m were prepared by the hydrothermal and post-annealing method. Then a circular Ti/Au electrode was patterned on  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs to fabricate solar-blind deep ultraviolet photodetectors. At zero bias, the device shows a photoresponsivity ( $R_\lambda$ ) of 10.80 mA W<sup>-1</sup> and a photo response time of 0.38 s under 254 nm light irradiation with a light intensity of 1.2 mW cm<sup>-2</sup>, exhibiting a self-powered characteristic. This study presents a promising candidate for use in solar-blind deep ultraviolet photodetection with zero power consumption.

## 1. Introduction

Solar-blind ultraviolet (UV) photodetectors (PDs) are useful as an answer to the technical challenge of operating at wavelengths less than 290 nm, while exposed to a large background radiation of sunlight. With the continuous improvement of device integration, environment complexity, and interference technology, solar-blind ultraviolet region photodetectors can effectively reduce false alarm rates in early-warning, searching, and tracking systems, to improve the accuracy and versatility of detection systems in various situations.<sup>1–5</sup> Up to now, a number of wide bandgap semiconductors have been investigated to design solar-blind photodetectors, such as AlGaN,<sup>6</sup> ZnMgO,<sup>7</sup>  $\beta$ -Ga<sub>2</sub>O<sub>3</sub>,<sup>8</sup> etc. AlGaN-based photodetectors present more excellent performance than the other wide bandgap semiconductors devices. However, with increasing Al composition for solar-blind detection, the performance of AlGaN photodetectors

rapidly becomes poor due to the obvious degradation of the crystal quality. ZnMgO alloys with a band gap in solar-blind region also suffer from the poor crystal quality due to the phase separation.<sup>9–11</sup>

It is noticed that Ga<sub>2</sub>O<sub>3</sub> has a direct wide bandgap of  $\sim$ 4.9 eV, directly corresponding to the wavelength less than 280 nm,<sup>12</sup> is an ideal solar-blind detection material without any doping and alloying process. Among all five phases of Ga<sub>2</sub>O<sub>3</sub> ( $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$  and  $\epsilon$ ), the  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> with monoclinic crystal structure is the thermally and chemically most stable phase, has been widely studied in solar-blind photodetectors.<sup>13–19</sup> So far,  $\beta$ -Ga<sub>2</sub>O<sub>3</sub>-based photodetectors mainly fall into three categories: film type, single crystals and nanorod arrays (NRAs) type. Compared to thin films, vertical nanowire array structures display more superior optical absorption ability and higher carrier generation, resulting from high surface-to-volume ratio and effective optical coupling, which can further improve the performance of photodetectors.<sup>20–23</sup> He *et al.*<sup>20</sup> first reported the ultraviolet photodetector based on vertical  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> nanowire arrays by thermally oxidizing GaN nanowires grown by molecular beam epitaxy (MBE) on Si substrate. Nevertheless, this complexity and high cost in fabrication will limit the practical application of  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs photodetector.

In this work, the vertically aligned  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs are successfully synthesized by economical hydrothermal and simple post-annealed method on fluorine doped tin oxide (FTO) substrate. And then a circular Ti/Au electrode was patterned on  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs to fabricate solar-blind deep ultraviolet photodetectors. The fabricated devices exhibited a great broadband spectral response with the high responsivity

exceeding  $550 \text{ A W}^{-1}$  at  $-5 \text{ V}$  bias voltage. At zero bias, the device shows a photoresponsivity ( $R_s$ ) of  $10.80 \text{ mA W}^{-1}$  and a photo response time of  $0.38 \text{ s}$  under  $254 \text{ nm}$  light irradiation with a light intensity of  $1.2 \text{ mW cm}^{-2}$ , exhibiting a self-powered characteristic. Our findings indicated that this simple synthesize method can be used to fabricate  $\beta\text{-Ga}_2\text{O}_3$  NRAs based self-powered solar-blind photodetectors with fast response speed for the potential applications in secure communication and space detection.

## 2. Experimental details

### 2.1 Materials

Ethanolamine ( $\text{C}_2\text{H}_7\text{NO}$ , 99%), gallium isopropoxide ( $\text{C}_9\text{H}_{21}\text{GaO}_3$ , 99%), gallium nitrate aqueous solution [ $\text{Ga}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$ , 10%] were purchased from Shanghai Saen

Chemical Technology Co., Ltd. Triethanolamine ( $\text{C}_6\text{H}_{15}\text{NO}_3$ , 78%) was obtained from Hangzhou Gaojing Fine Chemical Industry Co., Ltd. A fluorine doped tin oxide (FTO) with  $350 \text{ nm}$  conductive layer is used as a substrate. FTO conductive glass ( $14 \Omega \text{ cm}^{-2}$ , size:  $10 \times 20 \times 2.2 \text{ mm}^3$ ) was bought from Japan Nippon Sheet Glass Co., Ltd. All chemicals are analytical grade.

### 2.2 Synthesis and characterization of the $\beta\text{-Ga}_2\text{O}_3$ NRAs

The GaOOH NRAs were fabricated as described in our previous reports.<sup>24</sup> The substrate coated with  $\text{Ga}_2\text{O}_3$  seed layer was placed in the growth solution of  $\text{Ga}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  and heated at  $150 \text{ }^\circ\text{C}$  for  $12 \text{ h}$  in an oven. After the growth, the product was washed by DI water, dried in air at  $80 \text{ }^\circ\text{C}$ . The as-prepared GaOOH NRAs calcined at  $700 \text{ }^\circ\text{C}$  for  $4 \text{ h}$  were converted into the  $\beta\text{-Ga}_2\text{O}_3$  NRAs.

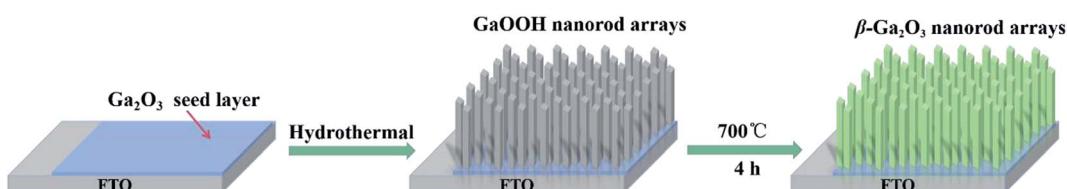

Fig. 1 Schematic illustration of preparation of the  $\beta\text{-Ga}_2\text{O}_3$  NRAs.

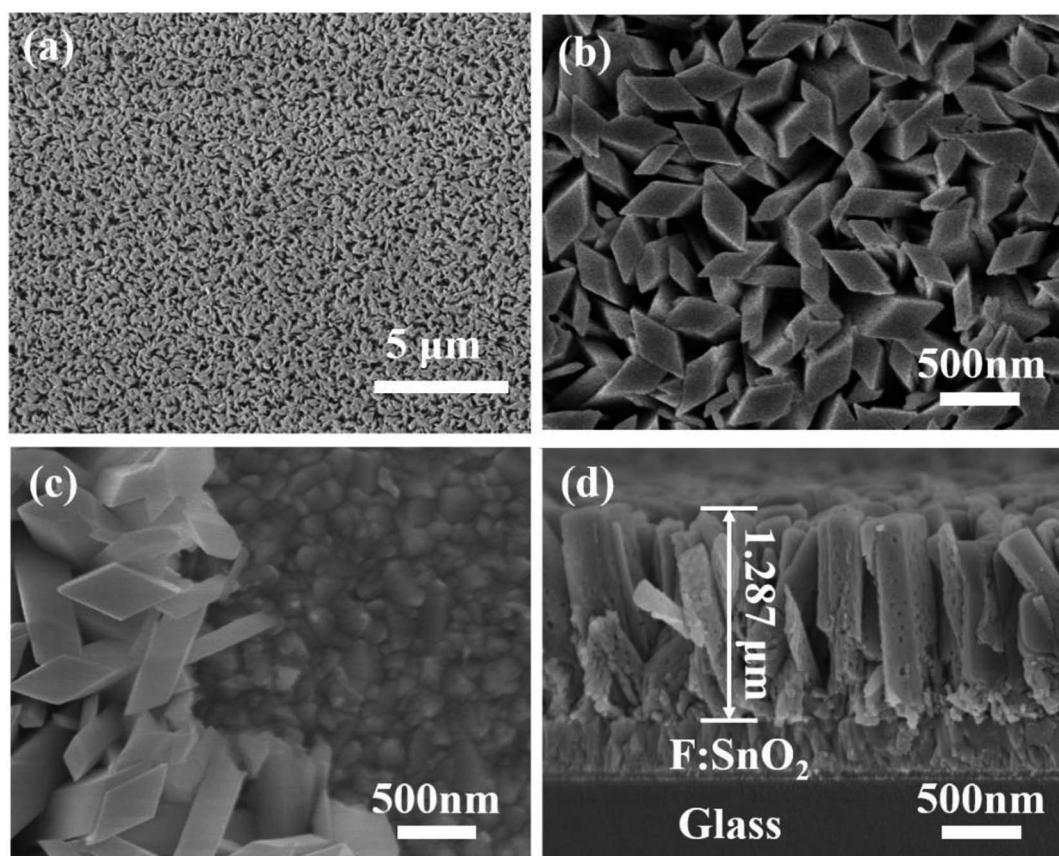

Fig. 2 The top views of SEM images at low (a) and high (b) magnification of  $\beta\text{-Ga}_2\text{O}_3$  NRAs grown on the FTO substrate. (c) The edge view of  $\beta\text{-Ga}_2\text{O}_3$  NRAs. (d) The cross-section of  $\beta\text{-Ga}_2\text{O}_3$  NRAs on the FTO substrate.

The morphologies of  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs were observed by a Hitachi S-4800 field-emission scanning electron microscope (SEM). The crystal structure of samples was analyzed by a Bruker D8 Advance X-ray diffractometer (XRD) using Cu K $\alpha$  radiation ( $\lambda = 0.154$  nm). The ultraviolet-visible (UV-vis) absorption spectrum was taken using a Hitachi U-3900 UV-vis spectrophotometer.

### 2.3 Fabrication and characterization of the photodetector

The photodetector was fabricated by depositing circular Ti/Au electrodes on the vertically aligned  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs with direct current magnetron sputtering. The photoelectric characteristics of the fabricated device were characterized by a Keithley 4200 at room temperature. And a 7 W lamp of 254 nm was used as the UV light source.

## 3. Results and discussion

The vertically aligned  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs have been grown on the FTO glass substrate and the fabrication process is schematically illustrated in Fig. 1. The  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs is fabricated by three steps procedure: (1) the seed layer was acquired by spin coating ethylene glycol monomethyl ether

solution of ethanolamine and gallium isopropoxide onto the FTO substrate; (2) the substrate coated with Ga<sub>2</sub>O<sub>3</sub> seed layer was placed in the growth solution of Ga(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O and heated at 150 °C for 12 h in an oven; (3) the as-prepared GaOOH NRAs calcined at 700 °C for 4 h were converted into the  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs.

The SEM result shows that a large-area, highly dense, and vertically aligned  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs have been successfully grown on the FTO glass substrate [Fig. 2(a-d)]. Fig. 2(a) displays a representative top-view SEM micrograph of as-synthesized  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> nanorods. Fig. 2(b) is a magnified image of Fig. 2(a). Fig. 2(c) is a top view SEM image in the boundaries of NRAs. Obviously, there has a high density and flat surface of  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs aligned vertically grown on FTO substrate. It also can be observed that the tips of the nanorods are the diamond shape, whose diameter has changed in the range of 100 to 500 nm. Fig. 2(d) shows the cross-section image of  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs on FTO substrate, we can estimate that the average length of nanorods is  $\sim 1.287$   $\mu$ m. Fig. 3(a) shows the XRD patterns of the FTO, FTO/GaOOH and FTO/ $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs, respectively. In addition to the diffraction peak of the FTO substrate, four peaks located at 35.3°, 37.4°, 62.3° and 66.7° were observed in FTO/GaOOH, which can be indexed to (021), (111), (002) and

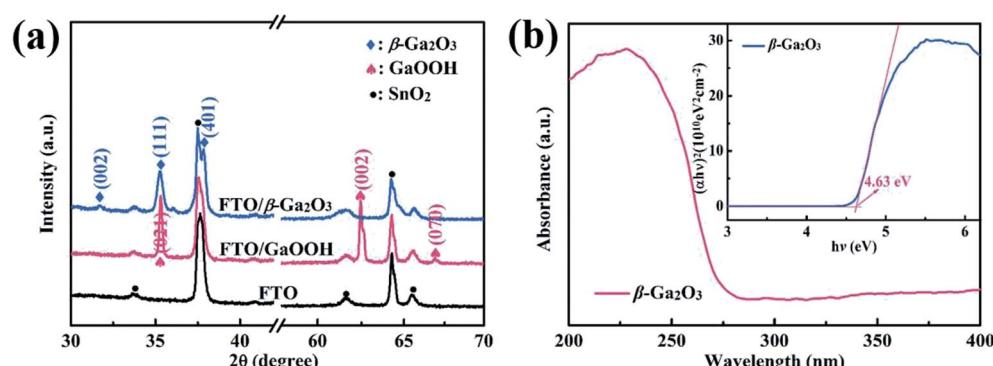

Fig. 3 (a) XRD patterns of the FTO, FTO/GaOOH NRAs and FTO/ $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs. (b) The absorption spectrum of  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> nanorod, the inset is  $(\alpha h\nu)^2$  versus  $h\nu$ .

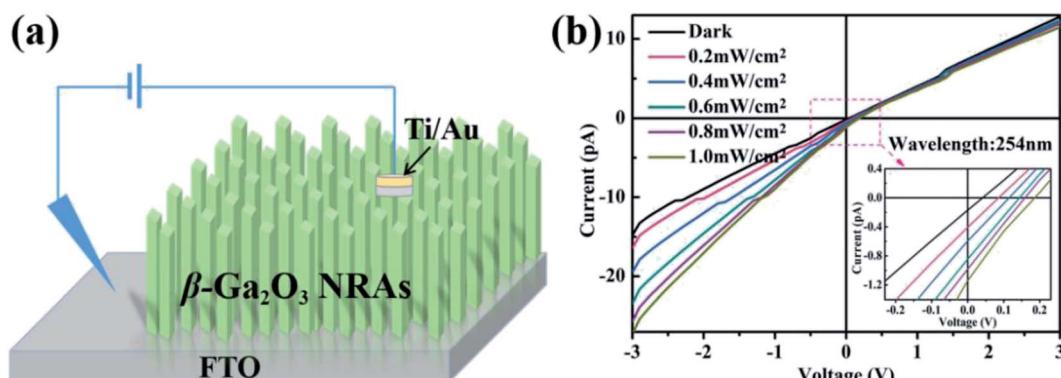

Fig. 4 (a) The schematic diagram of the  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs solar-blind photodetector. (b)  $I$ - $V$  curves of the device in dark and under 254 nm illumination with various light power densities.

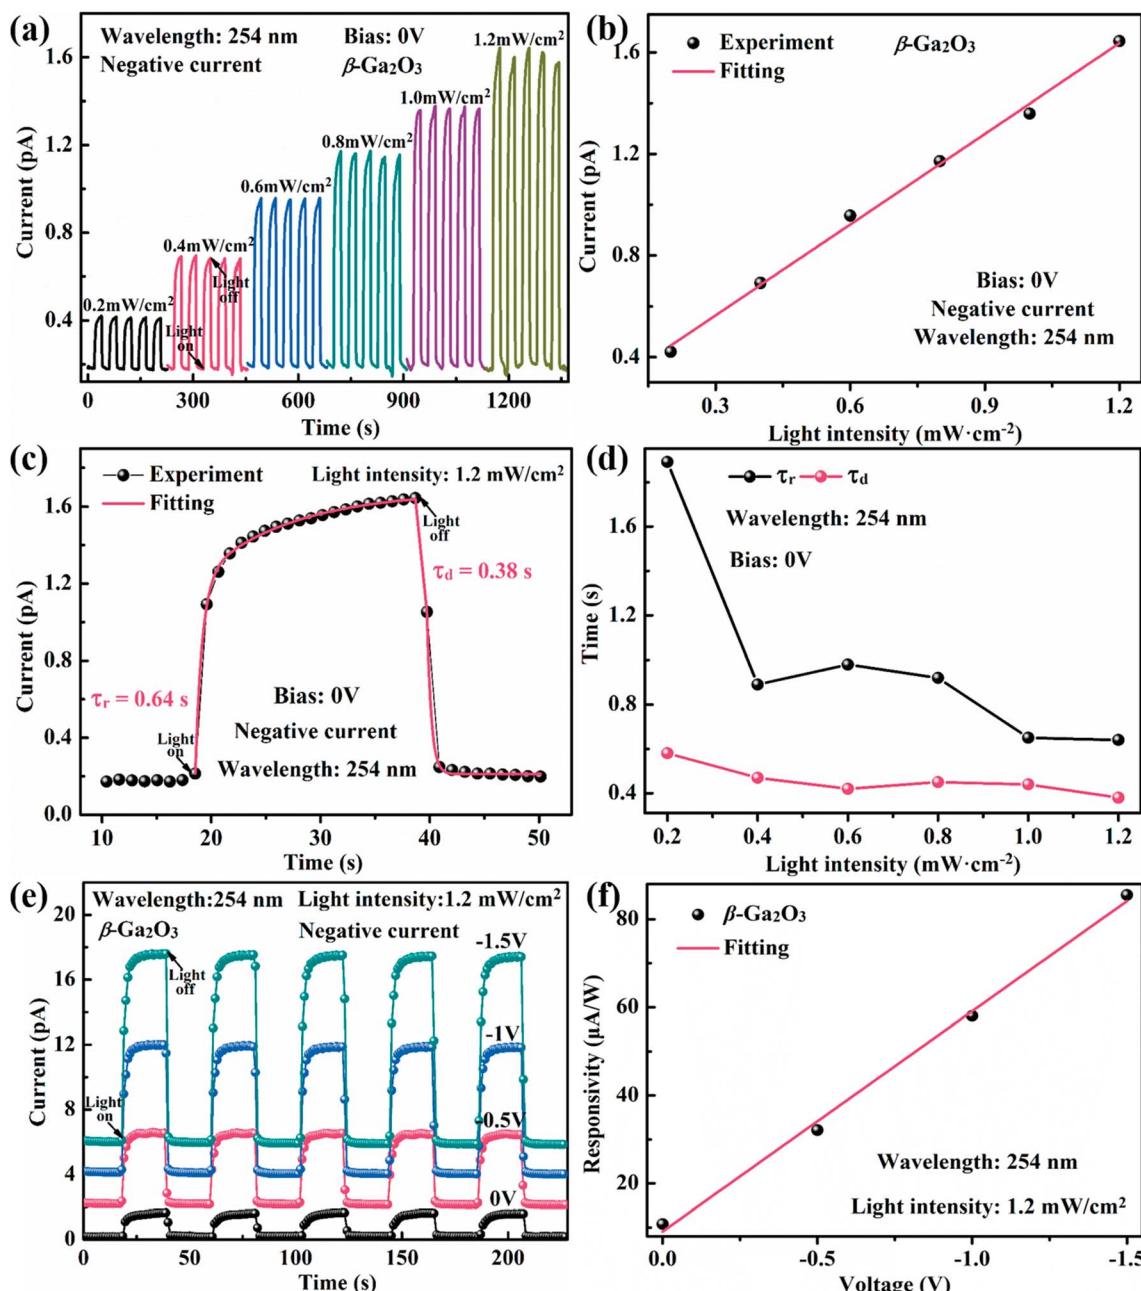

Fig. 5 (a)  $I-t$  curves of the device measured at 0 V bias under 254 nm illumination with various light intensities. (b) The relationship between the light intensity and photocurrent. (c) Rise time and decay time of the device at 0 V bias under 254 nm light irradiation with a light intensity of  $1.2 \text{ mW cm}^{-2}$ . (d) The relationship between the light intensity and photoresponse time. (e) The photoresponse switching behaviors of the device were measured at different applied bias voltages. (f) The relationship between the light intensity and applied bias voltage.

(070) crystal planes of orthorhombic GaOOH (JCPDS file no. 06-0180). The NRAs show a preferred growth orientation of [111] direction. After the annealing of as-prepared GaOOH NRAs, three additional peaks located at  $31.7^\circ$ ,  $35.3^\circ$  and  $37.9^\circ$  were observed, which can be ascribed to the (002), (111) and (401) planes of monoclinic  $\beta$  phase of  $\text{Ga}_2\text{O}_3$  (JCPDS file no. 41-1103).<sup>25</sup> The UV-vis absorbance spectra of the  $\beta\text{-Ga}_2\text{O}_3$  NRAs is shown in Fig. 3(b). It shows that the absorption onset of  $\beta\text{-Ga}_2\text{O}_3$  is at  $\sim 270$  nm. The optical bandgaps of  $\beta\text{-Ga}_2\text{O}_3$  NRAs can be determined based on the equation:  $(\alpha h\nu)^2 = A(h\nu - E_g)$ .

The energy bandgap ( $E_g$ ) is measured by linear extrapolation to the  $h\nu$ -axis. The  $(\alpha h\nu)^2$  versus  $h\nu$  curve of the  $\beta\text{-Ga}_2\text{O}_3$  NRAs is shown in the inset of Fig. 3(b), the band-gap of  $\beta\text{-Ga}_2\text{O}_3$  NRAs was estimated to be  $\sim 4.63$  eV, which is almost identical with previous reports.<sup>3,20</sup>

A circular Ti/Au electrode was patterned on  $\beta\text{-Ga}_2\text{O}_3$  NRAs to fabricate a solar-blind deep ultraviolet photodetector. The schematic diagram of the device is presented in Fig. 4(a). Fig. 4(b) depicts the current voltage ( $I-V$ ) curves of the device in dark and under 254 nm illumination with various light

**Table 1** Comparison of the device parameters of the present  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs based photoresponse parameters and other Ga<sub>2</sub>O<sub>3</sub> nanostructures based devices

Materials and structure	UV light	Bias voltage	$R$ (A W <sup>-1</sup> )	EQE (%)	Reference
Ga <sub>2</sub> O <sub>3</sub> nanorods	254	0.33	19.31	9427	24
Ga <sub>2</sub> O <sub>3</sub> nanowire	255	5	$3.43 \times 10^{-3}$	1.37	25
GaOOH nanorod	254	0.5	1.07	522	26
Ga <sub>2</sub> O <sub>3</sub> nanorods	254	0	$1.08 \times 10^{-2}$	$5.27 \times 10^{-3}$	This work

densities. Obviously, under the 254 nm ultraviolet illumination, the current in the reverse bias is larger than that in the forward bias. The inset of Fig. 4(b) is the enlarged curves around zero bias. It can be seen at 0 V bias that the current of the device increases in negative direction with the increase of the light densities, exhibiting a self-powered characteristic.

Fig. 5(a) shows the time-dependent photoresponse ( $I-t$ ) of the device measured at 0 V bias under 254 nm illumination with various light intensities. It exhibits stable and reproducible characteristics under an on/off interval of 20 s. The dark current is approximately  $-0.18$  pA. Under 254 nm light illumination, along with the light densities increased from 0.2 to 1.2 mW cm<sup>-2</sup>, the negative photocurrent value of device increase from 0.421 to 1.644 pA. The corresponding light/dark ratios ( $I_{\text{light}}/I_{\text{dark}}$ ) are gradually increased from 2.34 to 9.14. Notably, the photocurrent of the device linearly increases with the increase of the light intensities, as shown in Fig. 5(b), revealing that the stronger ultraviolet light can excite more photogenerated carriers.  $I-t$  curve of self-powered  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs solar-blind photodetector at 0 V bias under 1.2 mW cm<sup>-2</sup> 254 nm light irradiation is enlarged in Fig. 5(c). The rising and decaying edges were fitted by an exponential relaxation equation of the following type:

$$I = I_0 + A e^{-t/\tau_1} + B e^{-t/\tau_2} \quad (1)$$

where  $I_0$  is the steady state photocurrent,  $t$  is the time,  $A$  and  $B$  are constant,  $\tau_1$  and  $\tau_2$  are two relaxation time constants.  $\tau_r$  and  $\tau_d$  are the time constants for the rising edge and fall edge, respectively. The rise time ( $\tau_r$ ) and the decay time ( $\tau_d$ ) of are approximately 0.64 s and 0.38 s respectively.<sup>3</sup> It is noticed in Fig. 5(d) that  $\tau_r$  and  $\tau_d$  show downward trend with the increase of light intensity. The photoresponse switching behaviors of the device at different applied bias voltages were measured under 254 nm illumination as shown in Fig. 5(e). Apparently, both the dark current and photocurrent increases along with the increase of the bias voltages ranging from 0 V to  $-1.5$  V. Meanwhile, the photocurrent of 17.60 pA at  $-1.5$  V is about 11 times than that at 0 V under the same conditions. Notably, the photocurrent increases linearly with the increase of the electric field, because a more separation and transportation of electron–hole pairs would excite more pairs of the photo-generated electron–hole, resulting in a higher photocurrent. Photoresponsivity ( $R_\lambda$ ) and external quantum efficiency (EQE) are two important parameters to evaluate the sensitivity of PDs.  $R_\lambda$  is defined as the

photocurrent generated by per unit power of incident light on the effective area of a PD and EQE is bound up with the number of electron–hole pairs excited by a PD per adsorbed photon and per unit time.  $R_\lambda$  and EQE can be expressed in the following equations:

$$R_\lambda = \Delta I_\lambda / P_\lambda S \quad (2)$$

$$\text{EQE} = hcR_\lambda / (e\lambda) \quad (3)$$

where  $\Delta I_\lambda = I_\lambda - I_{\text{dark}}$  is the difference between photocurrent and dark current,  $P_\lambda$  is the incident light intensity,  $S$  is the effective illuminated area,  $h$  is the Planck's constant,  $c$  is the velocity of light,  $e$  is the electron charge, and  $\lambda$  is the incident light wavelength. It can calculate that the device exhibits a photoresponsivity ( $R_\lambda$ ) of 10.80 mA W<sup>-1</sup> and an external quantum efficiency (EQE) of  $5.27 \times 10^{-3}\%$  at 0 V bias under 1.2 mW cm<sup>-2</sup> 254 nm illumination. Simultaneously, the  $R_\lambda$  and EQE are estimated to 85.52 mA W<sup>-1</sup> and  $4.18 \times 10^{-2}\%$  for  $-1.5$  V bias, respectively. It can be seen from the Fig. 5(f) that  $R_\lambda$  increases near linearly with the bias voltage. Accordingly, applying bias voltage is a good way to rationally optimize the photoelectric performance of photodetector. For comparison, we list the photoresponse parameters of  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs PD and other types of devices reported in the literature in Table 1. It can be seen that compared with the other type device our device can work at zero bias. The  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs PD with a simple structure renders relatively high performance, wide absorption region and low fabrication cost, promising building high performance optoelectronic devices with a self-powered worked characteristic in the future.

## 4. Conclusions

In conclusion, a self-powered solar-blind photodetector was successfully fabricated by simple and low cost  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs growth process. The fabricated  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs based PD showed an obvious photoresponse in solar-blind ultraviolet region with good repeatability and stability. Under 0 V bias and 1.2 mW cm<sup>-2</sup> 254 nm illumination, the photodetector exhibits a  $I_{\text{light}}/I_{\text{dark}}$  ratio of 9.14, a  $R_\lambda$  of 10.80 mA W<sup>-1</sup>,  $\tau_r$  of 0.64 s and  $\tau_d$  of 0.38 s. The self-powered photodetector based on  $\beta$ -Ga<sub>2</sub>O<sub>3</sub> NRAs with high light-to-electron conversion and low power consumption abilities is a promising candidate for solar-blind photodetection application.
