The synthesis of five-membered cyclic carbonates via catalytic cycloaddition reaction of CO₂ with epoxides is considered to be an effective technology for alleviation of the energy crisis and global warming. Various commercial organic bases and ionic salts were used as catalysts, while the relationship of catalytic activity and compound structure has been seldom explored. Herein, a facilely obtained binary catalytic system based on triethylamine/NBu4Br was developed for CO₂ activation and chemical fixation. The highly efficient catalytic system showed outstanding conversion and above 99% selectivity under metal-free mild reaction conditions (100 °C, 1 atm) in one hour. The detailed process of CO₂ activation and chemical fixation was investigated at the molecular level by a series of experiments and theoretical calculation, which provided a mode for the design and synthesis of a highly efficient catalytic system for conversion of CO₂ under mild conditions.

Introduction

Carbon dioxide (CO₂) excessive emission is a main component of greenhouse gases in the atmosphere. Its conversion to value-added products has offered one promising way to alleviate the energy crisis and global warming. As an economical and abundant C₁ source, CO₂ is renewable, inexpensive and non-toxic, but its chemical inertness is still the bottleneck for its applicability as a raw material in industry. The catalytic synthesis of cyclic carbonate from epoxides and CO₂ is considered to be one of the most promising pathways to CO₂ utilization. Cyclic carbonates have wide applications as green polar aprotic solvents, fuel additives, and chemical intermediates. The chemical fixations of CO₂ into cyclic carbonates are relatively simple from a chemical reactivity point of view, while in fact, the high temperature, high pressure, high catalyst loading, or a combination of these are required to make the reaction effective, which is not economically suitable and poses safety concerns as well. To optimize the reaction conditions, a great variety of catalysts for the synthesis of cyclic carbonates have been developed so far, including alkali-metal halides, metal complexes, metal oxides, cellulose, MOFs, zeolites, ionic liquids, carbon nitride and so on. Though most catalysts were used to activate epoxide by a metal ion or hydrogen bond center, the effect of CO₂ activity on the reaction efficiency has rarely been studied deeply.

CO₂ is the highest oxidation state of carbon, and it is thermodynamically stable and kinetically inert, which will consequently hinder the development of efficient catalysts that achieve CO₂ activation and subsequently its functionalization. Thus the activation of CO₂ is pivotal for its effective conversion. The introduce/use of Lewis basic species and transition metal system have been highly considered, while the detailed CO₂ activation process was unclear so developing a catalytic system that provides molecular level insight for CO₂ activation process is still highly desired. Taking the aforementioned concerns into account, we propose to explore a new catalytic system that can activate and convert CO₂ with epoxides under mild conditions, and serve as an ideal mold for providing a detailed mechanistic understanding of CO₂ activation and fixation process.

Herein, a simple and efficient binary catalytic system based on organobase/NBu4Br was developed for CO₂ cycloaddition reaction with epoxides under metal-free mild conditions. It was found that the synergistic effect between two components in this new catalytic system promote the cycloaddition reaction occur under atmospheric pressure during a short time period of 1 hour. Moreover, the relationship of catalytic activity and catalyst structure was investigated at molecular level by a series of experiments and theoretical calculation, which could not only offer in-depth understanding of the reaction mechanism but also provide a theoretical basis for the effect of triethylamine (NEt₃) in activating CO₂ and promoting the reaction process.

Results and discussion

To understand the effects of the counter anions on the catalytic activity, the catalytic cycloaddition reaction of CO₂ with epoxides were initially investigated in the presence of 0.5 mL NEt₃. As shown in Table 1, NBu₄Br afforded a full conversion of 2-(chloromethyl)oxirane to 4-(chloromethyl)-1,3-dioxolan-2-one under 1.0 atm. CO₂ at 100 °C for 1.0 h (entry 1), and the catalytic conversion showed un conspicuous change when the NBu₄Br was replaced by NBu₄Cl, NBu₄I, respectively (entries 2–3). Notably, the yield of 2-(chloromethyl)oxirane to 4-(chloromethyl)-1,3-dioxolan-2-one decreased significantly when NBu₄PF₆ was used under the same condition, which is probably due to the weakest nucleophilicity of PF₆⁻ in selected Cl⁻, Br⁻, I⁻, and PF₆⁻, suggesting the counter anions play a dominant role in cycloaddition reaction of CO₂ with epoxides.39 When the common organic base NEt₃ was used alone under the same condition, 36% yield of 2-(chloromethyl)oxirane was obtained (entry 6), indicating that NET₃ can activate CO₂ in this reaction.40 Based on the above results, the high efficiency of the binary system is probably attributed to a synergistic effect between NBu₄Br and NEt₃ during the catalytic conversion of CO₂ with epoxides to cyclic carbonates.

Additionally, the influence of the basicity on the conversion of 2-(chloromethyl)oxirane was investigated in the presence of NBu₄Br with various organic bases at 100 °C for 1 h (Fig. 1a and b). As shown in Fig. 1b, the yield of 4-(chloromethyl)-1,3-dioxolan-2-one greatly related to the basicity of organic bases, and NEt₃ gave rise to the highest conversion of 2-(chloromethyl)oxirane to corresponding product due to its strongest alkalinity and minimum steric hindrance. The activities of organic bases decreased sharply from 99% to 92 and 63% when the pKa decrease from 18.8 to 10.2, respectively. As reported previously, the base was weaker, the ΔG of this reaction was lower,41 so the basicity order might be DIPEA > NEt₃ > TBA > TMEDA > MIm > Py > DMBA. However, the catalytic activity order of the organic bases is not in strict accordance with the established pKa, that was NEt₃ > TBA > Py > TMEDA > MIm > DIPEA > DMBA, which indicates that the basicity of the organic bases is one important factor for promoting catalytic activity, but the steric-hindrance also play a role in this catalytic reaction.23

**Fig. 1** Organic bases structures (a); the effect of organic bases on the yield of cyclic carbonate (b). pKa value of the conjugated acid in water which was obtained from the U.S. National Library of Medicine database.42 Reaction conditions: 2-(chloromethyl)oxirane (12.8 mmol), NBu₄Br (0.06 mmol), organic base (0.5 mL), CO₂ (1 atm), 100 °C, 1 h. The possibility of by-product was 3-chloro-1,2-propanediol.

The dependence of the cycloaddition reaction of CO₂ and 2-(chloromethyl)oxirane on temperature is shown in Fig. 2a. The results indicated that the activity of this catalytic system is highly dependent on the reaction temperature. In the lower temperature region (25 to 50 °C), the yield of 4-(chloromethyl)-

* Reaction conditions: 2-(chloromethyl)oxirane (12.8 mmol), NBu₄X (X = Br, Cl, F, PF₆) (0.06 mmol), NEt₃ (0.5 mL), CO₂ (1 atm), 100 °C. 
* Yield was determined by GC and ¹H NMR. The possibility of by-product was 3-chloro-1,2-propanediol.
1,3-dioxolan-2-one increases slowly with increasing temperature. A further increase in temperature from 50 to 100 °C has significant effects on the 2-(chloromethyl)oxirane conversion, and gave the target product in 99% GC yield at 100 °C for 1 h.

The kinetic curve for catalytic conversion of CO2 into cyclic carbonates was also investigated in the presence of NEt3/ NBu4Br at 100 °C. As shown in Fig. 2b, the yield of 4-(chloromethyl)-1,3-dioxolan-2-one increased rapidly in the first 40 min and then went up slowly. The complete consumption of 2-(chloromethyl)oxirane and synchronous formation of the desired product was achieved in 1 h. It should mentioned that the selectivity remains above 99% in the entire catalytic process.

It could be obviously seen that the reaction pressure showed a great effect on the cycloaddition reaction (Fig. 2c). With the increase of CO2 from 0.25 to 1 atm, the 4-(chloromethyl)-1,3-dioxolan-2-one yield increases from 20 to 99%. A further increase in the CO2 pressure from 1 to 1.5 atm results in a same level in 2-(chloromethyl)oxirane conversion. A similar effect of CO2 pressure on catalytic activity was observed in other related catalytic systems.43,44

The influence of NEt3 to NBu4Br ratio on the yield of 4-(chloromethyl)-1,3-dioxolan-2-one was also investigated at 100 °C for 1 h with fixed NBu4Br (0.06 mmol). As shown in Fig. 2d, when the ratio of NEt3 to NBu4Br increases from 1.6 to 18.2, the 4-(chloromethyl)-1,3-dioxolan-2-one yield increased rapidly. Then the 2-(chloromethyl)oxirane conversion stayed almost constant when ratio of NEt3 to NBu4Br increased further.

The excellent catalytic activity encouraged us to further explore the generality of the catalytic system, and several epoxides with different steric and electronic characters were tested. The results show that the various diverse epoxides were converted to the corresponding cyclic carbonates in high yields and excellent selective by this effective catalytic system (Table 2). The complete conversion of 2-(chloromethyl)oxirane is attributed to the presence of electron-withdrawing –CH2Cl group (entry 1), which facilitates nucleophilic attack of halide anions during the ring opening of the oxirane. The catalytic system is still effective for the epoxides with long alkyl carbon chain, such as 2-butyloxirane, 2-(ethoxymethyl)oxirane and 2-((allylox)ethyloxirane (entries 2–4). The reactivity of epoxides with aromatic substituent is similar to that of long alkyl carbon chain (entries 5, 6). Interestingly, the complete conversion of 2,2′-(((propane-2,2-diylbis(4,1-phenylene))bis(oxirane))bis(methylene))bis(1,3-dioxolan-2-one) could be achieved in 18 h (entry 7).

To further understand the underlying principles of CO2 activation, the computation by the DFT (M06-2X) calculations was studied. Preliminary calculations indicated no involvement of NBu4+ cation (Fig. S1 in ESI†), which was consequently neglected from the elaborate calculations reported herein.37

* Reaction conditions: epoxide (12.8 mmol), NBu4Br (0.06 mmol), NEt3 (0.5 mL), CO2 (1 atm), 100 °C. Yield was determined by GC and 1H NMR. The possibility of by-products were corresponding diols.
When the reaction was calculated in NEt₃ solution, there
different mechanisms were revealed (Fig. 4). The bromide-
catalyzed process (black energy profile shown in Fig. 4) in
NEt₃ solution shows the same transition states and intermediates
as in gas-phase. But the energy barrier of rate-determining
step is 31.1 kcal mol⁻¹, which is 8.8 kcal mol⁻¹ larger this
procedure without NEt₃ solvent. Also the carbonate ring-closure
step (cTS2) in NEt₃ solution has an energy of 18.2 kcal mol⁻¹,
which is 7.4 kcal mol⁻¹ larger than bromide-catalyzed process
in gas. For comparison, we also calculated the reaction with
NET₃ as catalyst in the absence of bromide (red profile). The
NET₃-catalyzed epoxide ring-opening procedure has a high
energy barrier (cTS1, 42.4 kcal mol⁻¹, red profile in Fig. 4),
which is 11.3 kcal mol⁻¹ larger than bromide-catalyzed transition
state in NEt₃ solution. Afterwards, the CO₂ addition step to
form cTS2 has an energy of 46.0 kcal mol⁻¹ relative to the energy
of the reactants. Finally, this mechanism of ring-closure process
may undergo a cTS3 transition states, which has an energy of
44.7 kcal mol⁻¹ above the reactants. However, the energy barrier
of 42.4 kcal mol⁻¹ is quite high and consistent with a sluggish reaction and unable to take place under mild experimental conditions,⁴⁸ indicating that NEt₃ does not merely act as
a solvent but also influences the course of the reaction. Thus,
the mechanism when NET₃ participation tends to a bromine and
NET₃ jointly catalyzed process (blue profile shown in Fig. 4),
a new intermediate C1 appears, resulting from the CO₂ addition
upon interaction with NET₃ and bromine. This rate-determining
step presented no transition states and has an energy of
17.5 kcal mol⁻¹ the above reactants, 4.8 kcal mol⁻¹ energy
favorable than pure bromine-catalyzed process in gas-phase,
13.8 kcal mol⁻¹ decrease than bromine-catalyzed procedure in
NET₃ solvent, which allows the reaction to be performed under
mild conditions. A potential energy surfaces scan calculation
based on C1 intermediate validates transition states non-
existent (Fig. S3 in ESI†). It is conceivable that the ring-
opening of epoxide and CO₂ addition might undergo synchro-
nously with two catalysts. Afterwards, ring-closure takes place
through cTS1. NET₃ then dissociates from the reacting system,
which reverts to A₁ and evolves to product through aTS2 with
a free energy of 27.7 kcal mol⁻¹ above the reactants. The
calculated rate constant is 1.850 × 10⁻³ s⁻¹ at 373 K. Then the
expering half-life is ten minute, which accord with the experimental data. The intermediate of A₁ with C₁ were selected
to compare the structure changes in reaction, the C–O bond
of CO₂ change slightly as shown in Fig. S4, while the C–O bond between C atom of CO₂ moiety and O atom of epoxide moiety
decreases from 1.46 Å to 1.43 Å, then the interaction between
CO₂ and epoxide moieties enhanced with NET₃ as solution and
catalyst. Moreover, the Mulliken charge of carbon atom of CO₂
moiety decreases from 0.3 to 0.07 when compared C₁ with A₁.
Therefore, the bond length and charge analysis suggest that the lone pair electron of nitrogen in NET₃ stabilized the formation of C₁ and cTS1.

Overall, a plausible mechanism for triethylamine-promoted
catalytic conversion of CO₂ into cyclic carbonates has been
proposed based on the aforementioned results (Fig. 5). First, the
epoxide ring opens through nucleophilic attack on the less
sterically hindered β-carbon atom by Br⁻ to produce an alkoxide
ion, and simultaneously CO₂ is activated by NET₃ via electrostatic
interaction to form the carbamate salt. Then a new intermediate
C₁ is produced resulting from the nucleophilic attack on carba-
mate salt by alkoxide ion. Finally, cyclic carbonate is produced
by following intramolecular ring-closure reaction of C₁.
Conclusions

An efficient binary catalytic system containing triethylamine and NBu4Br was screened for catalytic conversion of CO2 and epoxides into cyclic carbonates under metal-free mild conditions. Especially, NEt3 could activate CO2 via electrostatic interaction and remarkably reduce the reaction energy to promote the reaction in the catalytic system. This work not only presents a simple and useful route for CO2 chemical fixation into high-value chemicals, but provides a detailed mechanistic understanding of CO2 activation and fixation process.

Experimental

General

Chemicals including NEt3, NBu4Br, NBu4Cl, NBu4I, NBu4PF6, epoxides and CO2 are commercially available and used directly without further purification. Gas chromatography (GC) was performed on a Shimadzu GC-2014 equipped with a capillary column (RTX-5, 30 m × 0.25 μm) using a flame ionization detector.

Typical catalytic reaction

The cycloaddition reaction was carried out by magnetic stirring, trimethylamine (0.5 ml), NBu4Br (0.06 mmol) and 2-(chloromethyl)oxirane (12.8 mmol) were added into a reactor at room temperature. Then, the reactor was sealed and purged with CO2 to remove air. CO2 was introduced into the reactor and the pressure was adjusted to 1 atm at room temperature. The reactor was placed into pre-heated oil bath and temperature was maintained at 100 °C. After the reaction was completed, the reactor was cooled to 0 °C in ice-water bath, and then the excess of CO2 was carefully vented. The mixture was diluted with ethyl acetate. The conversion of epoxide and yield of cyclic carbonate were determined by gas chromatography (Shimadzu GC-2014, a flame ionization detector) and 1H NMR.

Computational details

The M06-2X functional was employed in this article to perform all the calculations. Our structure optimizations were as follows. In NBu4Br involved reaction, only gas-phase calculations were performed. For carbonate formation with bromine as catalyst, the structures were firstly optimized base on the level of 6-31+G(d,p) in gas-phase, then the solvent structure optimizations were carried out based on gas-phase results. As for the rest of other structure optimizations, the calculations were performed in solvent. Vibrational frequency analyses at the same basis sets were used on all optimized structures in order to characterize stationary points as local minima or transition states. Furthermore, the intrinsic reaction coordinate (IRC) calculations at the same level have been applied to validate that transition states connect appropriate reactants and products. The Gibbs free energy were further calculated by single-point energy calculations using M02-2X/6-31+G(d,p) method on previously 6-31+G(d,p) structures and thermal corrections at 298.15 K and 1 atm. No conformational sampling calculations were performed in this work. The continuum SMD model was applied. The Gaussian 09 package was used for all of our calculations in NEt3 solvent.
