## Fully automated peptide radiolabeling from [ $^{18}\text{F}$ ] fluoride†

Ryan A. Davis,<sup>a</sup> Chris Drake,<sup>b</sup> Robin C. Ippisch,<sup>c</sup> Melissa Moore<sup>b</sup> and Julie L. Sutcliffe<sup>a</sup>

The biological properties of receptor-targeted peptides have made them popular diagnostic imaging and therapeutic agents. Typically, the synthesis of fluorine-18 radiolabeled receptor-targeted peptides for positron emission tomography (PET) imaging is a time consuming, complex, multi-step synthetic process that is highly variable based on the peptide. The complexity associated with the radiolabeling route and lack of robust automated protocols can hinder translation into the clinic. A fully automated batch production to radiolabel three peptides (YGGFL, cRGDyK, and Pyr-QKLGNGWAVGHLM) from fluorine-18 using the ELIXYS FLEX/CHEM® radiosynthesizer in a two-step process is described. First, the prosthetic group, 6- $^{18}\text{F}$ fluoronicotinyl-2,3,5,6-tetrafluorophenyl ester ( $^{18}\text{F}$ FPy-TFP) was synthesized and subsequently attached to the peptide. The  $^{18}\text{F}$ FPy-peptides were synthesized in 13–26% decay corrected yields from fluorine-18 with high molar activity 1–5 Ci  $\mu\text{mol}^{-1}$  and radiochemical purity of >99% in an overall synthesis time of  $97 \pm 3$  minutes.

## Introduction

Peptide-based pharmaceuticals have applications in both diagnostic imaging and targeted therapy with more than 60 approved by the US Food and Drug Administration (FDA), ~140 in clinical trials (half of which are diagnostic imaging agents), and approximately another 500 in pre-clinical development.<sup>1,2</sup> Peptides have numerous characteristics that make them ideal as radiotracers; in particular, their biological half-life ideally matches the radioactive half-life of many radionuclides currently being used for positron emission tomography (PET), such as gallium-68, fluorine-18, and copper-64.<sup>3</sup> They are relatively small in size (~0.5 to 10 kDa) and exhibit short *in vivo* circulation times (min to h) that result in rapid clearance from the blood pool and non-targeted tissues.<sup>4</sup> Peptides have demonstrated similar binding affinities as antibodies for their respective targets but are simpler to prepare, typically non-immunogenic, and can be easily chemically modified to further improve affinity, selectivity, stability, and their pharmacokinetic profile.<sup>3</sup> Moreover, contemporary molecular biology and peptide combinatorial library techniques allow large peptide libraries to be generated and rapidly screened

against a target epitope, facilitating identification and optimization of high affinity peptide ligands.<sup>5</sup>

One of the first examples of a peptide radiotracer translated to the clinic was [ $^{123}\text{I}$ ]-Tyr<sup>3</sup>-octreotide, used to image somatostatin receptor density in patients with neuroendocrine tumors (NETs).<sup>6</sup> Octreotide was later optimized and radiolabeled with indium-111 for single photon computed tomography (SPECT), and since then octreotide has been radiolabeled with PET-radionuclides including gallium-68 and fluorine-18, offering greater sensitivity and higher resolution images that provide for a more accurate diagnosis.<sup>6–11</sup> Somatostatin imaging has become the standard-of-care for patients with NETs, with sensitivities and specificities of >90%, and the combination of somatostatin imaging with computed tomography (CT) or magnetic resonance imaging (MRI) has been reported to change clinical treatment for 20–60% of patients.<sup>11</sup> The FDA approval of NETSPOT ( $^{68}\text{Ga}$ -DOTATATE) in 2016 underscores the success of peptide radiotracers currently used in the clinic.<sup>12</sup>

Several other disease associated cellular-receptors have been targeted with peptide radiotracers for both imaging and radiotherapy. For example the integrin- $\alpha_v\beta_3$ , which is overexpressed in a number of cancers, including melanoma, breast, and head and neck as well as neo-angiogenic blood vessels.<sup>13–16</sup> The integrin- $\alpha_v\beta_3$  is involved in a number of cellular processes, including cell proliferation, migration, and tumor metastasis, and has been widely studied as a target for both imaging and therapy using small peptides containing an arginine-glycine-aspartic acid (RGD)-motif.<sup>13–19</sup> Another member of the integrin family of receptors that is currently being investigated is the integrin- $\alpha_v\beta_6$ , an epithelial-specific cell surface receptor that is

undetectable in healthy adults, but is significantly up-regulated in a wide range of epithelial derived cancers including, pancreas, colon, non-small cell lung cancer, ovarian, breast, prostate, and oral squamous cell carcinoma.<sup>20–26</sup> Sutcliffe *et al.*, have focused significant effort on the development of  $\alpha_v\beta_6$ -targeting peptides based on the 20 amino acid sequence derived from an envelope protein of the foot-and-mouth disease virus.<sup>23–26</sup> Another example are the gastrin releasing peptide receptors (GRPRs) that are overexpressed in many cancers, including breast, pancreatic, and prostate, with GRPR-mediated signalling being linked to several oncogenic processes such as invasiveness and proliferation.<sup>27,28</sup> These receptors have been targeted by a series of bombesin peptides for both imaging and therapeutic purposes with their efficacy being examined in several clinical studies.<sup>27,28</sup>

Fluorine-18 is a favored radioisotope for radiolabeling peptides due to its nuclear and physiochemical characteristics for *in vivo* imaging, including a half-life (109.77 min) that closely matches the pharmacokinetics of peptides, low  $\beta^+$  energy (0.64 MeV), high 97%  $\beta^+$  emission, and is readily available in sufficient quantities (10–20 Ci) and high molar activity (1–10 Ci  $\mu\text{mol}^{-1}$ , required for receptor-targeting imaging).<sup>29,30</sup> Radiolabeling of peptides with fluorine-18 is mainly carried out using a prosthetic group, a small, bifunctional molecule that is first reacted with the radioisotope with subsequent attachment to the peptide at the *N*-terminal amine, the *N* $\epsilon$ -amine of a lysine residue, or a thiol of a cysteine residue.<sup>4</sup> Examples of amine-reactive prosthetic groups include *N*-succinimidyl 4- $^{18}\text{F}$ fluorobenzoate ( $^{18}\text{F}$ SFB), 4- $^{18}\text{F}$ fluorobenzoic acid ( $^{18}\text{F}$ FBA), and 6- $^{18}\text{F}$ fluoronicotinic acid 2,3,5,6-tetrafluorophenyl ester ( $^{18}\text{F}$ FPy-TFP).<sup>4</sup> Thiol-reactive prosthetic groups include maleimide-containing moieties such as *N*-[2-(4- $^{18}\text{F}$ fluorobenzamido)ethyl]maleimide ( $^{18}\text{F}$ FBEM) and *N*-[6-(4- $^{18}\text{F}$ fluorobenzylidene)aminooxyhexyl]maleimide ( $^{18}\text{F}$ FBAM).<sup>4</sup> Non-canonical functional groups can also be incorporated into peptides to facilitate radiolabeling using  $^{18}\text{F}$ -prosthetics such as 4- $^{18}\text{F}$ fluorobenzaldehyde, 2- $^{18}\text{F}$ fluorodeoxyglucose ( $^{18}\text{F}$ FDG), and click-moieties such as  $^{18}\text{F}$ fluoro-*trans*-cyclooctene.<sup>29,30</sup> The use of a prosthetic group to radiolabel peptides from fluorine-18 is generally required as direct incorporation into the peptide is not feasible due to the harsh reaction conditions required for C–F bond formation (*e.g.* high temperatures or strongly basic conditions).<sup>4</sup> Traditionally, synthesis of the prosthetic group is performed manually.<sup>31</sup>

Automation of the radiosynthesis can provide a safe, reproducible, straight-forward route to radiolabel any peptide from fluorine-18. Unfortunately to date automated procedures have primarily focused on small molecules or the production of prosthetic groups.<sup>4</sup> Several automated syntheses of  $^{18}\text{F}$ -prosthetics used for peptide radiolabeling have been reported, including  $^{18}\text{F}$ SFB,<sup>32</sup>  $^{18}\text{F}$ FBEM,<sup>32</sup>  $^{18}\text{F}$ FBA,<sup>32</sup> azido- $^{18}\text{F}$ fluoro-sugars,<sup>33</sup>  $^{18}\text{F}$ hexafluorobenzene,<sup>34</sup> and  $^{18}\text{F}$ fluoroethylazide.<sup>35</sup> The radiochemical yields for these automated productions are comparable, if not better than the analogous manual protocols.<sup>32–35</sup> Automated protocols capable of generating  $^{18}\text{F}$ -peptides from fluorine-18 without manual interventions are less prevalent, as multiple purifications are typically needed for

both the intermediate  $^{18}\text{F}$ -prosthetic and the final  $^{18}\text{F}$ -peptide radiotracer.<sup>4,31</sup> For example, Thonon *et al.*, used the FASTLab™ GE synthesis module for the production of  $^{18}\text{F}$ SFB *via* both a one- and two-pot method, followed by coupling to an RGD peptide (PRGD2).<sup>36</sup> Ackermann *et al.* also reported the fully automated radiolabeling of the protein glutathione with  $^{18}\text{F}$ FBEM the thiol reactive prosthetic group on an iPHASE FLEX-Lab module, however no extension of this methodology to radiolabeling a clinically-relevant peptide was included in this paper.<sup>37</sup> Both methods required some form of manual intervention, and to our knowledge a fully automated procedure for the radiosynthesis of a clinically relevant fluorine-18 radiolabeled peptide has yet to be reported.<sup>4</sup> Therefore, the goal of this work was to develop a fully automated  $^{18}\text{F}$ -peptide radiolabeling synthesis and apply it to three clinically relevant peptides (YGGFL (1), cRGDyK (2), and Pyr-QKLGNQWAVGHLM (3)) (Fig. 1) with no user intervention. To achieve this, the  $^{18}\text{F}$ FPy-TFP prosthetic group was synthesized on an ELIXYS FLEX/CHEM® radiosynthesizer automated module and subsequently conjugated to each of the target peptides.

## Experimental

### General

Solvents and reagents were purchased from Acros Organics (Pittsburg, PA), Sigma Aldrich (St Louis, MO), and NovaBiochem (Darmstadt, Germany) unless otherwise stated, and used without further purification. All solvents used for automated synthesis were anhydrous extra dry over molecular sieves. Chromatography solvents were purchased from EMD Millipore (Chicago, IL) as HPLC-grade and used directly. All automated syntheses were performed on an ELIXYS FLEX/CHEM® radiosynthesizer (Sofie Co., Culver City, CA) using the exact same command sequence (S1). The  $^{19}\text{F}$ -reference standards were synthesized using commercially available 6-fluoronicotinic acid (TCI America, Portland, OR) and/or 2,3,5,6-tetrafluorophenol (Sigma-Aldrich, St. Louis, MO). These synthon's C12-RP-HPLC is provided for reference (S2 and S3) as they are the major by-products observed during hydrolysis of the  $^{18}\text{F}$ FPy-TFP prosthetic group. Rink-amide resin, *N*-terminal fluorenylmethoxycarbonyl (Fmoc) protected amino acids and 1-[bis(dimethylamino)methylene]-1*H*-1,2,3-triazolo[4,5-*b*]pyridinium 3-oxid hexafluoro-phosphate (HATU) were purchased from GL Biochem (Shanghai, China) or NovaBiochem (Darmstadt, Germany). The peptides used for radiolabeling, cRGDyK (2) and Pyr-QKLGNQWAVGHLM (3) (Fig. 1) were purchased from AnaSpec (Fremont, California) and used without further purification. The fluorine-18 was produced by PETNET Solutions (Sacramento, California). The aqueous fluoride-18 (6–10 mCi per synthesis) was trapped onto a chromafix-PS-HCO<sub>3</sub> anion exchange cartridge (Macherey-Nagel, Düren, Germany) (conditioned with 2 mL water). Purification cartridges C18-SepPak-Plus and Oasis MCX-Plus-mixed cation exchange cartridge were purchased from Waters (Milford, MA, USA) (conditioned with 10 mL ethanol followed by 10 mL water).

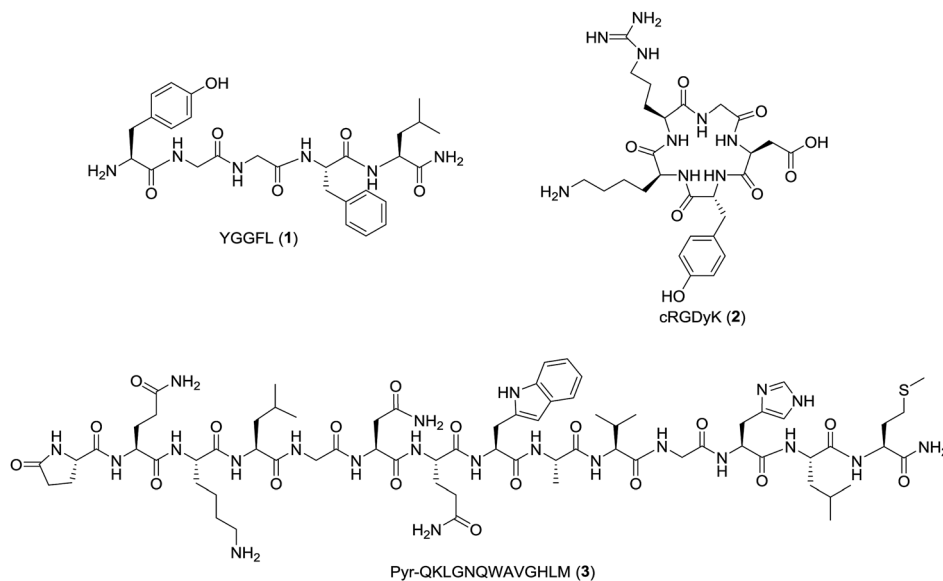

Fig. 1 Structures of the target peptides.

### HPLC conditions

All peptides were purified and characterized using C12-RP-HPLC using a Beckmann Coulter Gold HPLC system equipped with a 2 mL loop and a C12-Phenomenex-Jupiter 5  $\mu$ m Proteo 90 Å column (250  $\times$  4.6 mm, 4  $\mu$ m) with an ultraviolet (UV) absorbance detector (220 nm) and radioactivity detector (photomultiplier tube; Bioscan) connected in series. Mobile phase solvents were 0.05% trifluoroacetic acid in water (solvent A) and 100% acetonitrile (solvent B) with a gradient starting from 100% solvent A to 10% solvent B over 2 min, then to 90% solvent B over 10 min, held at 90% B for 5 min, then returned to 100% solvent A over 5 min, held at 100% solvent A for 3 min with a flow rate of 1.5 mL min<sup>-1</sup>.

### PyTFP-precursor (4) and <sup>19</sup>Fpy-TFP reference standard synthesis

The precursor *N,N,N*-trimethyl-5-((2,3,5,6-tetrafluorophenoxy)carbonyl)pyridine-2-ammoniumfluoromethanesulfonate (4, Scheme 1) was synthesized using the slightly modified procedure as described by Olberg *et al.*<sup>38</sup> 6-Chloronicotinic acid (5.2 g, 33.0 mmol) was activated with *N,N*-dicyclohexylcarbodiimide (DCC, 10.22 g, 49.51 mmol) in THF (100 mL) for 5 minutes followed by dropwise addition of 2,3,5,6-tetrafluorophenol (6.58 g, 39.61 mmol) in THF (35 mL) and reacted overnight. The precipitate of *N,N*-dicyclohexylurea was removed by filtration and the reaction contents concentrated, washed with a saturated solution of sodium bicarbonate in dichloromethane, concentrated under reduced pressure and purified by silica-gel chromatography with a gradient solvent system starting from 10%-ethyl acetate in *n*-hexanes increasing to 50%-ethyl acetate in *n*-hexanes. The resulting ester (7.8 g, 25.57 mmol) was dissolved in THF (100 mL), stirred vigorously while trimethylamine gas was bubbled through the reaction for 3 hours and stirred overnight. The reaction contents were then concentrated and

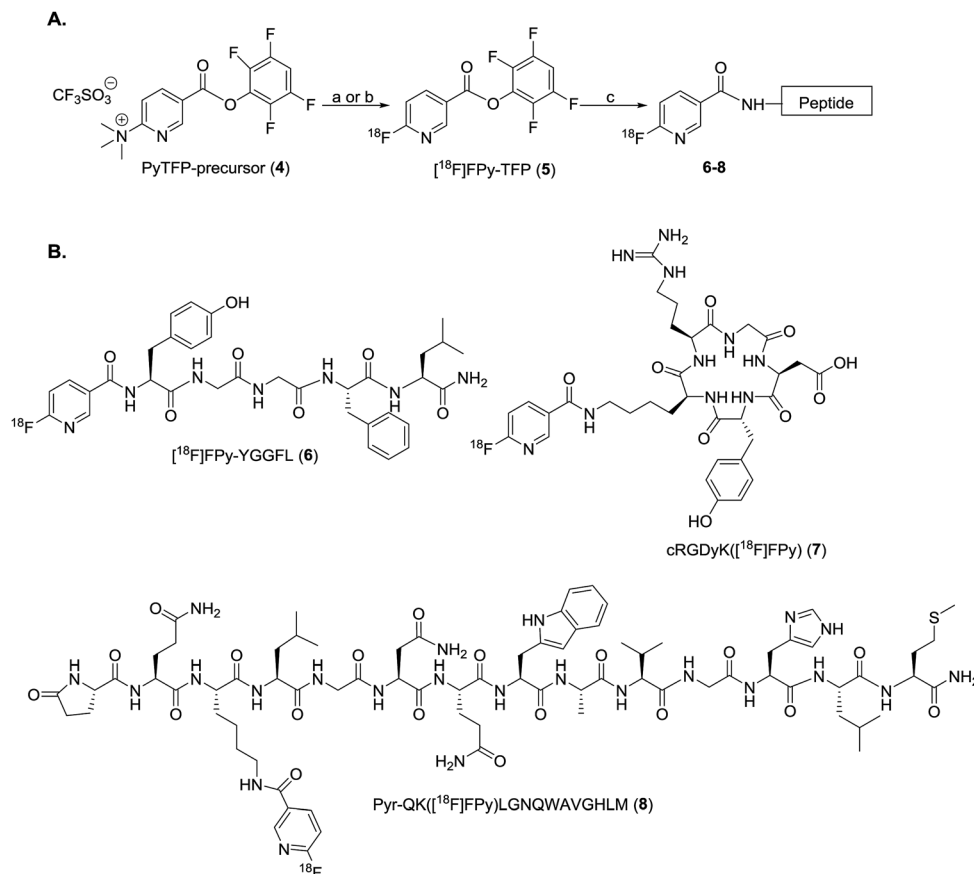

the solid washed with diethyl ether. The resulting solid was suspended in dichloromethane (200 mL) and stirred vigorously while trimethylsilyl trifluoromethanesulfonate (TMSOTf, 10 g, 44.99 mmol) was added dropwise *via* a syringe. The suspension was stirred for 15 min and the unreacted material filtered off with the reaction contents concentrated under reduced pressure and the resulting precipitate triturated with diethyl ether (50 mL). The product was collected by suction filtration and rinsed with diethyl ether (50 mL  $\times$  3). An X-ray crystal structure was obtained to confirm counter anion exchange<sup>39</sup> and the HPLC retention time of the precursor (4) was 8.93 min (S4).

The <sup>19</sup>Fpy-TFP reference standard was prepared as previously described by Olberg *et al.*,<sup>38</sup> 6-fluoronicotinic acid (200 mg, 1.4 mmol) was reacted with DCC (439 mg, 2.1 mmol) in THF (4 mL) for 5 minutes followed by dropwise-addition of 2,3,5,6-tetrafluorophenol (285 mg, 1.7 mmol) dissolved in THF (2 mL). After stirring overnight, the dicyclohexylurea was filtered off, the solvent concentrated, and the resulting <sup>19</sup>Fpy-TFP ester purified by silica-gel column chromatography in 90%-*n*-hexanes and 10%-ethyl acetate. The <sup>19</sup>Fpy-TFP ester reference standard was characterized per previous literature<sup>38</sup> and had an HPLC-retention time of 13.73 min (S5).

### Peptide synthesis of YGGFL (1)

The NH<sub>2</sub>-YGGFL peptide (1, Fig. 1) was assembled on rink amide resin using traditional solid-phase fluorenylmethyloxycarbonyl (Fmoc)-chemistry with reiterative couplings (1.5 h) with Fmoc-amino acids (3 equiv.), HATU (2.8 equiv.) and DIPEA (6 equiv.) and Fmoc removal (2  $\times$  15 min) with 20%-piperidine in *N,N*-dimethylformamide (DMF, 1 mL).<sup>40,41</sup> Coupling and deprotection was monitored with a picryl sulfonic acid colorimetric test.<sup>41</sup> After assembly, the peptide was globally deprotected and cleaved from the resin using tri-fluoroacetic acid/triisopropylsilane/water (TFA/TIPS/H<sub>2</sub>O, 95/

**Scheme 1** (A) Radiolabeling of peptides with  $^{18}\text{F}$ FPy-TFP (5). (B) Structures of radiolabeled  $^{18}\text{F}$ FPy-peptides (6–8). Reagents and conditions: (a)  $^{18}\text{F}$ FPy,  $\text{K}_{222}$ ,  $\text{K}_2\text{CO}_3$ , 4 : 1 tBuOH : MeCN, 40 °C, 10 min or (b)  $^{18}\text{F}$ FPy, TBA-HCO<sub>3</sub>, 4 : 1 tBuOH : MeCN, 40 °C, 10 min. (c) Peptide (1 mg), DMSO, DIPEA, 40 °C, 15 min.

2.5/2.5, v/v/v, 1 mL, 3 h) and purified by HPLC. The purified peptide (NH<sub>2</sub>-YGGFL (1)) was characterized by HPLC and high resolution electrospray ionization mass spectrometry (HR-ESI-MS) in positive mode on an Orbitrap (Thermo-Fisher Scientific, San Diego, CA, USA). The HPLC retention time was 7.48 min (S9) and the HR-ESI-MS  $m/z$ :  $[\text{M} + \text{H}]^+$  calc'd for C<sub>28</sub>H<sub>39</sub>N<sub>6</sub>O<sub>6</sub> 555.2926; found 555.2906 (S10).

### <sup>19</sup>FPy-peptide reference standards

**<sup>19</sup>FPy-NH-YGGFL-CONH<sub>2</sub>.** The <sup>19</sup>FPy-YGGFL reference standard was prepared using peptidyl resin (25 mg). The *N*-terminal Fmoc was removed by 20% piperidine in DMF (2 × 15 min) and 6-fluoronicotinic acid (10 mg) added *via* activation with HATU (10 mg) and DIPEA (25 μL) in DMF (1 mL). The peptidyl resin was allowed to react for 1.5 h before being rinsed with DMF (3 ×) followed by methanol (3 ×) and dried on the lyophilizer (1 h). The peptide was globally deprotected and cleaved from the resin with TFA/TIPS/H<sub>2</sub>O (95/2.5/2.5, v/v/v, 1 mL, 3 h) and purified by HPLC and characterized by both HPLC and high resolution electrospray ionization mass spectrometry (HR-ESI-MS) in positive mode on an Orbitrap (Thermo-Fisher Scientific, San Diego, CA, USA). The retention time of [<sup>19</sup>F]FPy-YGGFL-CONH<sub>2</sub>

was 9.52 min (S11) and the HR-ESI-MS  $m/z$ :  $[\text{M} + \text{H}]^+$  calc'd for C<sub>34</sub>H<sub>41</sub>FN<sub>7</sub>O<sub>7</sub> 678.3046; found 678.3048 (S12).

**cRGDyK(<sup>19</sup>FPy).** Following previously reported protocol,<sup>42</sup> cRGDyK was synthesized and cyclized on resin preloaded with the aspartic acid (D), connected *via* its side-chain and protected as the allyl ester for orthogonal deprotection and cyclization. The sidechain *Nε*-amine of the lysine residue was protected with 1-(4,4-dimethyl-2,6-dioxocyclohex-1-ylidene)-3-methylbutyl (ivDde) protecting group, that was removed with hydrazine after cyclization. The cRGDyK peptidyl resin was coupled with 6-fluoronicotinic acid (10 mg) by reaction with HATU (10 mg) and DIPEA (50 μL) in DMF (1 mL) for 1.5 h and cleaved from the resin with TFA/TIPS/H<sub>2</sub>O (95/2.5/2.5, v/v/v, 1 mL, 3 h). The reference standard cRGDyK(<sup>19</sup>FPy) was HPLC purified and characterized by HPLC and high resolution electrospray ionization mass spectrometry (HR-ESI-MS) in positive mode on an Orbitrap (Thermo-Fisher Scientific, San Diego, CA, USA). The retention time of cRGDyK(<sup>19</sup>FPy) was 7.30 min (S16) and the HR-ESI-MS  $m/z$ :  $[\text{M} + \text{H}]^+$  calc'd for C<sub>33</sub>H<sub>44</sub>FN<sub>10</sub>O<sub>9</sub> 743.3271; found 743.3269 (S17).

**Pyr-QK(<sup>19</sup>FPy)LGNQWAVGHLM.** The bombesin peptide (Pyr-QKLGNGWAVGHLM (3, Fig. 1), 0.25 mg) was reacted in solution DMF (200 μL) with HATU (5 mg), DIPEA (25 μL), and 6-fluoronicotinic acid (5 mg) for 2 h. The peptide was then purified by

HPLC and characterized by HPLC and matrix assisted laser desorption ionization time of flight mass spectrometry (MALDI-TOF-MS) with a matrix of sinapinic acid (Sigma Aldrich, St. Louis, MO, USA). The HPLC retention time of Pyr-QK( $^{19}\text{F}$ Py) LGNQWAVGHLM was 8.40 min (S21) and the MALDI-TOF-MS  $m/z$ :  $[\text{M} + \text{H}]^+$  calc'd for  $\text{C}_{77}\text{H}_{113}\text{FN}_{23}\text{O}_{19}\text{S}$  1714.8282; found 1715.1168 (S22).

### Description of ELIXYS FLEX/CHEM® radiosynthesizer set up

All radiosyntheses were carried out on an ELIXYS FLEX/CHEM® radiosynthesizer (Fig. 2). The ELIXYS FLEX/CHEM® radiosynthesizer has three identical, independent reactors that support heating and cooling (room temperature to 200 °C) with stirring capabilities. The reactors move in the Y, Z-direction to engage with a universal disposable reagent cassette, which can hold up to 12 different reagents (36 for full system) of 3 mL volume in disposable septum sealed vials. The disposable cassette houses all reagents paths, and tubing assemblies for routing liquid, including two external addition ports, and an inlet for delivery of aqueous fluoride-18. Additionally, the underside of the cassette mates with the reactor v-vial at various positions for robot arm-assisted reagent addition (ADD REAGENT, 2 positions), gas and vacuum assisted evaporation (EVAPORATE, 1 position), fully-sealed reactions (REACT, 2 positions, supporting up to 150 psi),<sup>43</sup> and transfer of contents out of the reactor v-vial to various other positions in the synthesizer (TRANSFER, 1 position).

The reactor v-vial is monitored at all times by a live camera feed displayed on the graphical user interface of the software. Likewise, radioactivity within the system is monitored by radiation sensors positioned throughout the system. The reagents, their location, and the cassettes used are listed in Table 1 for the automated peptide radiolabeling with [ $^{18}\text{F}$ ]FPy-TFP (5). The synthesis program ("sequence"), consisting of individual "unit operations" wherein specific conditions (temp., inert gas

pressure *etc.*) can be defined, was created for the synthesis of the [ $^{18}\text{F}$ ]FPy-peptides (6–8) from [ $^{18}\text{F}$ ]fluoride *via* conjugation with [ $^{18}\text{F}$ ]FPy-TFP (5) (S1†). The ELIXYS radiosynthesizer was configured with two identical cassettes for each  $^{18}\text{F}$ -peptide radiosynthesis that were connected *via* an external gross dilution vessel (25 mL-pear shaped round bottom sealed with rubber septum) to enable the high volume dilution (15 mL) required for trapping of [ $^{18}\text{F}$ ]FPy-TFP (5) on the SPE-cartridge. This dilution vessel was connected inline between reactors 1 and 2 and positioned before the purification MCX-cartridge. A small stir-plate was placed under the dilution vessel to enable stirring of the reaction mixture during the dilution step. The first cassette was joined from the "T" position on cassette 1 into the gross dilution vessel containing an outlet line composed of a long stainless steel syringe needle (150 mm) positioned at the bottom of the dilution flask leading out of the flask with the SPE-cartridge inline that feeds back into cassette 1 at the "C2-O" position, allowing for the dilution volume and SPE-washes to be directed to the waste. Cassette 1 was attached to cassette 2 from the "O" position of cassette 1 into the "I-1" position on cassette 2.

### ELIXYS FLEX/CHEM® radiosynthesizer synthesis of [ $^{18}\text{F}$ ]FPy-TFP (5) and radiolabeling of peptides

**Synthesis of [ $^{18}\text{F}$ ]FPy-TFP (5).** A solution of [ $^{18}\text{F}$ ]fluoride in O-18 water (~1 to 2 mL, 6–10 mCi) was delivered into the system using 5 psi positive nitrogen gas pressure and trapped onto a PS-HCO<sub>3</sub> anion exchange cartridge. The radioactivity was eluted from the cartridge into reactor 1 with either (i) kryptofix (K<sub>222</sub>, 20 mg) and potassium carbonate (K<sub>2</sub>CO<sub>3</sub>, 4 mg) in 94 : 6 acetonitrile : water (MeCN : H<sub>2</sub>O, 2 mL), or (ii) 0.075 M tetrabutylammonium bicarbonate (TBA-HCO<sub>3</sub>, 300  $\mu\text{L}$ , ABX, GmBH, Radeburg, Germany) solution in 94 : 6 MeCN : H<sub>2</sub>O (2 mL) (reagent cassette 1, position 1). After azeotropic drying with acetonitrile (1 mL  $\times$  2, reagent cassette 1, positions 2 and 3) under vacuum and constant stirring, the precursor 4 (10 mg,

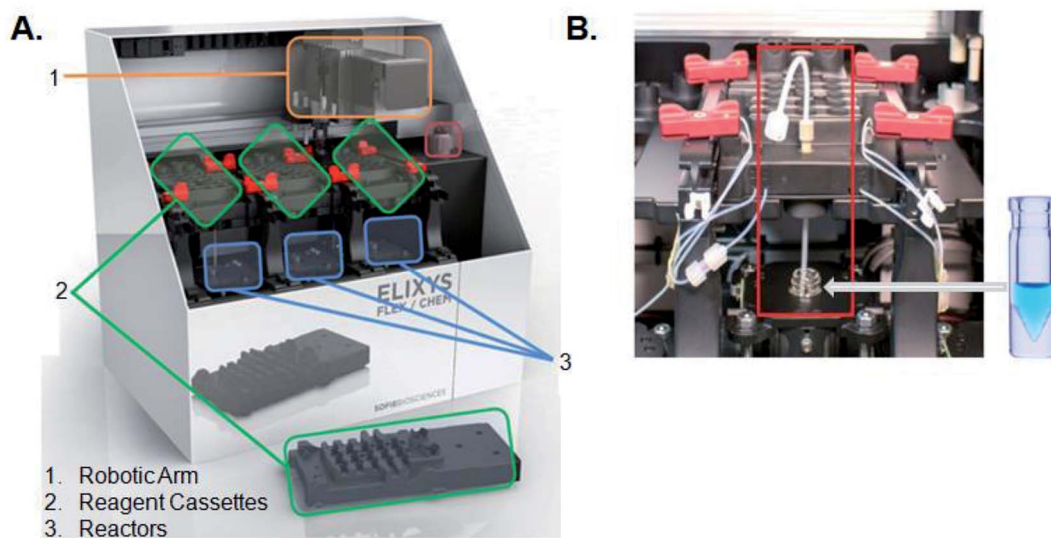

Fig. 2 (A) ELIXYS FLEX/CHEM® radiosynthesizer (B) zoom-in of a reagent cassette above one of the reactors containing the v-vial.

**Table 1** List of reagents in each reagent cassette of the ELIXYS FLEX/CHEM® radiosynthesizer

| Cassette # | Reagent position | Reagent   |
|------------|------------------|---|
| 1          | 1                | $K_{222}/K_2CO_3$ (20 mg/4mg) in 94 : 6 MeCN : H <sub>2</sub> O (2 mL) <sup>a</sup> |
| 1          | 2                | 1.0 mL MeCN   |
| 1          | 3                | 1.0 mL MeCN   |
| 1          | 4                | [ <sup>18</sup> F]Py-TFP precursor (4, 10 mg) in 4 : 1 <i>t</i> BuOH : MeCN (1 mL)  |
| 1          | 5                | 2.5 mL water  |
| 1          | 6                | 2.5 mL water  |
| 1          | 7                | 3.0 mL MeCN   |
| 2          | 1                | Peptide (1 mg) in 0.5 mL DMSO and 10 $\mu$ L DIPEA                                  |

<sup>a</sup> TBA-HCO<sub>3</sub> (0.075 M, 300  $\mu$ L) in 94 : 6 MeCN : H<sub>2</sub>O (2 mL) was also used to elute fluoride-18 as another alternative with both methods providing identical results.

Scheme 1), dissolved in 4 : 1 *t*BuOH : MeCN (1 mL) (reagent cassette 1, position 4), was added to reactor 1 and heated to 40 °C for 10 min with constant stirring. After reaction completion, an aliquot (100–200  $\mu$ L) was taken out of the reaction, diluted to 1 mL with solvent A and the crude reaction mixture analyzed by analytical radio-HPLC (S6).

**Purification of [<sup>18</sup>F]FPy-TFP (5).** After formation of [<sup>18</sup>F]FPy-TFP (5), the crude reaction mixture was transferred from reactor 1 into the dilution vessel, pre-loaded with 15 mL of water; the diluted mixture was then passed through an MCX SPE cartridge, trapping [<sup>18</sup>F]FPy-TFP (5). The cartridge was then rinsed with water (5 mL, reagent cassette 1, positions 5 and 6) by first adding water in 2 portions to reactor 1, and then transferring it into the external dilution vessel and through the cartridge. Similarly, the [<sup>18</sup>F]FPy-TFP (5) was eluted off the MCX-cartridge with acetonitrile (MeCN, 3 mL, reagent cassette 1, position 7) (Fig. 3) into reactor 2, where the solvent was removed in preparation for peptide coupling. During method development, various preconditioned SPE-cartridges (C18 SepPak-Plus cartridge (Waters) and Oasis MCX-Plus cartridge (Waters) and their respective combinations) were explored for the purification of [<sup>18</sup>F]FPy-TFP (5). The diluted crude [<sup>18</sup>F]FPy-TFP (5) reaction mixture was trapped on four different SPE-cartridge combinations (MCX, C18SepPak, MCX-C18SepPak, and

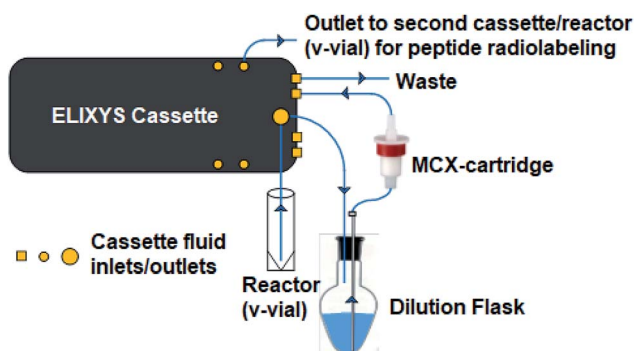

C18SepPak-MCX), eluted in acetonitrile, analysed by analytical radioHPLC (S7) and identity confirmed by co-injection with [<sup>19</sup>F]Py-TFP reference standard (S8). In each case, the SPE-cartridges were positioned per Fig. 3.

**Synthesis of [<sup>18</sup>F]FPy-peptides (6–8).** Peptides (NH<sub>2</sub>-YGGFL (1), cRGDyK (2), or Pyr-QKLGNGWAVGHLM (3), 1.0 mg, 1.8  $\mu$ mol, 1.6  $\mu$ mol, and 0.6  $\mu$ mol respectively, Fig. 1) were dissolved in 0.5 mL dimethylsulfoxide (DMSO) and DIPEA (10  $\mu$ L, reagent cassette 2, position 1) and added to the dried down MCX-purified [<sup>18</sup>F]FPy-TFP (5) in reactor 2 (Scheme 1). The reaction was heated at 40 °C for 15 min with constant stirring. The crude reaction mixture was diluted to ~1.2 mL with solvent A and injected remotely onto an analytical radio-HPLC (S13, S18, and S23). The purified radiolabeled peptide was collected, radioactivity measured, and then re-injected onto the analytical radioHPLC to assess overall yield and purity of final product (S14, S19 and S24). The molar activity was determined by injection of known amounts of each of the nonradioactive [<sup>19</sup>F]Py-peptide reference standard and comparing the HPLC integration of the UV-peak (220 nm) to the associated UV-peak (220 nm) of the radioactive peak of the corresponding [<sup>18</sup>F]FPy-peptide (6–8). The identity of all radiolabeled [<sup>18</sup>F]FPy-peptides (6–8, Scheme 1) was confirmed by co-elution with non-radioactive [<sup>19</sup>F]Py-peptide reference standards (S15, S20 and S25).

## Results

### Synthesis of [<sup>18</sup>F]FPy-TFP (5) on ELIXYS FLEX/CHEM® radiosynthesizer

[<sup>18</sup>F]FPy-TFP (5) was generated in decay-corrected yields of 76.1  $\pm$  3.5% ( $n$  = 6) after MCX-cartridge purification with a synthesis time of 42  $\pm$  6 minutes (Scheme 1). Radiofluorination utilized 10 mg of the PyTFP-precursor (4), heated with [<sup>18</sup>F]fluoride for 10 minutes at 40 °C in *t*BuOH : MeCN (4 : 1, v/v). Purification was achieved using a single MCX-SPE-cartridge; an external gross dilution vessel was required to sufficiently dilute the crude reaction mixture prior to trapping on the SPE, however no manual intervention was required. Identical yields of [<sup>18</sup>F]FPy-TFP (5) were obtained using either  $K_{2.2.2}$  (10 mg mL<sup>-1</sup>) and  $K_2CO_3$  (2 mg mL<sup>-1</sup>) in a mixture of MeCN and H<sub>2</sub>O (94 : 6, v/v; 2 mL), or TBAHCO<sub>3</sub> (300  $\mu$ L of a 0.075 M solution) in the same solvent system.

**Fig. 3** Diagram of gross dilution set-up. Set-up allows [<sup>18</sup>F]FPy-TFP (5) purification via a 15 mL water dilution in an external flask, trapping on an Oasis MCX cartridge followed by a 5 mL water wash and 3 mL acetonitrile elution. All operations are fully automated via ELIXYS FLEX/CHEM® radiosynthesizer and no manual interventions required.

### Purification of [ $^{18}\text{F}$ ]FPy-TFP (5)

Purification of [ $^{18}\text{F}$ ]FPy-TFP (5) was required to remove excess unreacted PyTFP-precursor (4) and to limit formation of by-product 2,3,5,6-tetrafluorophenyl-6-(2,3,5,6-tetrafluorophenoxy)nicotinate (11) (Fig. 4).<sup>38</sup> Both PyTFP-precursor (4) and by-product (11) can compete with [ $^{18}\text{F}$ ]FPy-TFP (5) for peptide conjugation, hindering the radiochemical yield of [ $^{18}\text{F}$ ]FPy-peptides. The purification of [ $^{18}\text{F}$ ]FPy-TFP (5) was explored using various SPE cartridge(s) (C18 SepPak-Plus cartridge, Oasis MCX-Plus cartridge, and combinations of the two) by monitoring UV impurities by HPLC. The crude HPLC-chromatogram of the [ $^{18}\text{F}$ ]FPy-TFP (5, Fig. 5A, peak  $\blacktriangle$ ) showed large amounts of unreacted PyTFP-precursor (4, Fig. 5A, peak \*), along with 2,3,5,6-tetrafluorophenol (9, Fig. 5B, peak  $\blacksquare$ ), no by-product (11) was observed as previously by Olberg *et al.*<sup>38</sup> Purification *via* MCX-cartridge removed excess PyTFP-precursor (4) (Fig. 5B), with the only remaining impurity being the UV-impurity of 2,3,5,6-tetrafluorophenol (9, Fig. 5B, peak  $\blacksquare$ ). Further attempts to improve the purification using combinations of C18 SepPak-Plus and Oasis MCX-Plus cartridges in series, did not afford higher purities than the MCX-cartridge alone. In fact, all dual-cartridge purification systems examined, led to a higher percentage of hydrolysis of [ $^{18}\text{F}$ ]FPy-TFP (5, Fig. 5C, peak  $\blacktriangle$ ), as demonstrated by increased amounts of 6-[ $^{18}\text{F}$ ]fluoronicotinic acid (Fig. 5C, peak  $\bullet$ ). In summary, a single Oasis MCX-Plus cartridge provided the optimal purification and had the best elution efficiencies (>80%) with minimal hydrolysis of [ $^{18}\text{F}$ ]FPy-TFP (5) to 6-[ $^{18}\text{F}$ ]fluoronicotinic acid.

### Synthesis of [ $^{18}\text{F}$ ]FPy-peptides (6–8) *via* ELIXYS FLEX/CHEM® radiosynthesizer

Coupling of peptides (1–3, Fig. 1) to purified [ $^{18}\text{F}$ ]FPy-TFP (5) was achieved *via* reaction with 1 mg of peptide in 0.5 mL DMSO and 10  $\mu\text{L}$  of DIPEA at 40  $^{\circ}\text{C}$  for 15 min. Purified [ $^{18}\text{F}$ ]FPy-peptides (6–8, Scheme 1) were obtained from [ $^{18}\text{F}$ ]fluoride in a total synthesis time of  $97 \pm 3$  minutes, and with decay corrected yields (including 25 min HPLC purification) ranging between 13–26% ( $n = 4$ ). Radiochemical purities were high (>99%, Table 2), and molar activities ranged from 1–5 Ci  $\mu\text{mol}^{-1}$ . The crude radioHPLC chromatogram for each peptide (S13, S18 and S23) showed only two radiochemical peaks,

corresponding to the radiolabeled [ $^{18}\text{F}$ ]FPy-peptide (Fig. 6A, peak  $\blacklozenge$ ) and hydrolyzed [ $^{18}\text{F}$ ]FPy-TFP (5) to 6-[ $^{18}\text{F}$ ]fluoronicotinic acid (Fig. 6A, peak  $\bullet$ ). Fig. 6B is a representative HPLC chromatogram of purified radiolabeled [ $^{18}\text{F}$ ]FPy-YGGFL (6) peptide's co-injected with its [ $^{19}\text{F}$ ]FPy-YGGFL peptide reference standard (S15, S20, and S25), showing that all radiolabeled peptides could be purified to >99% radiochemical purity.

## Discussion

The unique properties of receptor-targeting peptides, such as their high target affinity, rapid clearance from the circulation, and relative ease of synthesis, has made them attractive agents for both receptor imaging and targeted radiotherapy.<sup>3,4</sup> With favorable nuclear and physiochemical characteristics,  $^{18}\text{F}$ -radiolabeled receptor-targeting peptides have shown great promise as imaging agents in oncology. However, there remains an unmet need to develop a reliable, reproducible, fully automated approach that is amenable to cGMP guidelines and can be applied to a wide range of peptides.<sup>4</sup> Therefore, the goal of this work was to develop a fully automated radiolabeling protocol to generate  $^{18}\text{F}$ -peptides from [ $^{18}\text{F}$ ]fluoride requiring no manual user interventions, using [ $^{18}\text{F}$ ]FPy-TFP and the ELIXYS FLEX/CHEM® radiosynthesizer.

The [ $^{18}\text{F}$ ]FPy-TFP prosthetic group is an activated ester prepared in a single step from [ $^{18}\text{F}$ ]fluoride with a single cartridge based purification, and can be coupled to any peptide bearing a free amine, either at the *N*-terminus or at the *N $\epsilon$*  on a lysine residue in the peptide sequence.<sup>38</sup> To date, the batch production of [ $^{18}\text{F}$ ]FPy-TFP and subsequent peptide radiolabeling has been carried out using manual synthesis techniques.<sup>38,44–46</sup> Although Olberg, Malik, and others have demonstrated the effectiveness of the [ $^{18}\text{F}$ ]FPy-TFP prosthetic group for radiolabelling various peptides, intermediate purification of the [ $^{18}\text{F}$ ]FPy-TFP was required prior to conjugation to a peptide in order to remove unreacted PyTFP-precursor that interferes with peptide radiolabeling.<sup>38,44–46</sup> In addition, Olberg *et al.* showed that hydrolysis of the PyTFP-precursor resulted in formation of 2,3,5,6-tetrafluorophenyl-6-(2,3,5,6-tetrafluorophenoxy)nicotinate (by-product (11)), which can hinder efficient radiolabeling of the peptide.<sup>38</sup> To facilitate purification, the ELIXYS FLEX/CHEM® radiosynthesizer can

Table 2 Summary of  $^{18}\text{F}$ Py-TFP (5) radiolabeling yields of peptides (1–3)

| Peptide | Amount                      | % Yield <sup>a</sup> | Radiochemical purity |
|---------|-----------------------------|----------------------|----------------------|
| 6       | 1.0 mg, 1.8 $\mu\text{mol}$ | 25.6 $\pm$ 2.7       | >99%                 |
| 7       | 1.0 mg, 1.6 $\mu\text{mol}$ | 16.0 $\pm$ 5.6       | >99%                 |
| 8       | 1.0 mg, 0.6 $\mu\text{mol}$ | 13.0 $\pm$ 5.2       | >99%                 |

<sup>a</sup> Radiochemical decay corrected yields from  $^{18}\text{F}$ fluoride of purified radiolabeled peptide reported as the average yield  $\pm$  SD ( $n = 4$ ).

accommodate SPE-cartridges in multiple configurations, enabling intermediate cartridge based purifications within the reaction sequence. However, in order to purify  $^{18}\text{F}$ FPy-TFP, the initial organic reaction mixture required dilution with 15 mL water prior to trapping on the SPE-cartridge. To achieve this a pre-filled external vessel was incorporated upstream of the Oasis MCX-SPE-cartridge, with minimal modifications to the ELIXYS FLEX/CHEM® radiosynthesizer system. As a result,  $^{18}\text{F}$ FPy-TFP was produced with average yields of  $76.1 \pm 3.5\%$  and sufficiently high radiochemical and chemical purities. These yields are comparable to other automated  $^{18}\text{F}$ -prosthetics group productions used for peptide radiolabeling. For example, the automated synthesis of  $^{18}\text{F}$ FBEM on an Eckert & Ziegler module took 95 minutes to afford a  $17.3 \pm 7.1\%$  non-decay corrected yield.<sup>47</sup> The automated synthesis of  $^{18}\text{F}$ SFB on a TRACERlab FX<sub>FN</sub> synthesizer (GE Healthcare) produced non-decay corrected yields ranging from 25–35% in 40 minutes.<sup>48</sup> Thonon, *et al.* also automated the synthesis of  $^{18}\text{F}$ SFB to yield 42% decay corrected yield in 57 minutes on a FASTLab™ (GE Healthcare).<sup>36</sup> Other  $^{18}\text{F}$ -prosthetics such as  $^{18}\text{F}$ FBEM,  $^{18}\text{F}$ SFB, and  $^{18}\text{F}$ F-TCO were previously produced with decay

corrected yields of  $35 \pm 8\%$  (98 min),  $69 \pm 8\%$  (78 min), and  $44 \pm 9\%$  (71 min) respectively, using the ELIXYS FLEX/CHEM® radiosynthesizer.<sup>32</sup>

Radiolabeling of peptides with  $^{18}\text{F}$ FPy-TFP were previously performed manually using a variety of peptide coupling conditions.<sup>38,44–46</sup> The original manual peptide radiolabeling with  $^{18}\text{F}$ FPy-TFP by Olberg *et al.* utilized a 1 : 1 : 1 DMSO : MeCN : phosphate buffer (pH-9.0), 3–5 mg of peptide, and a reaction temperature of 40 °C for 15 minutes to generate the  $^{18}\text{F}$ FPy-peptide in a  $22.5 \pm 6.0\%$  yield (total synthesis time = 85 minutes).<sup>38</sup> Malik *et al.* manually radiolabeled a DUPA-peptide (2 mg) with  $^{18}\text{F}$ FPy-TFP in 5 : 3 MeCN : H<sub>2</sub>O, containing 5.5 mg of sodium bicarbonate as a base, at 60 °C for 10 minutes, resulting in a  $48 \pm 0.9\%$  non-decay corrected yield (total synthesis time = 50 minutes).<sup>44</sup> Basuli *et al.* manually reacted 3–5 mg of peptide at 50 °C for 10 minutes with  $^{18}\text{F}$ FPy-TFP in a 2.75 : 2.5 : 1 mixture of MeCN : H<sub>2</sub>O : *t*BuOH containing either 10–15 mg of sodium bicarbonate or 5  $\mu\text{L}$  of triethylamine, generating the  $^{18}\text{F}$ -peptide in non-decay corrected yields of 25–43% (total synthesis time = 30 minutes).<sup>45,46</sup> To avoid solubility issues and the potential to clog lines and needles of the automated system, DIPEA was used over sodium bicarbonate as the base. DMSO was selected as a solvent, as previous literature suggested that peptide conjugation in buffers seemed to result in lower yields.<sup>36</sup> Using these conditions, acceptable radiochemical yields (13–26%) were achieved using minimal amounts of peptide (1 mg).

The radiolabeling yields for YGGFL using the ELIXYS FLEX/CHEM® radiosynthesizer were  $25.6 \pm 2.7\%$  and were comparable to the previously reported radiolabeling yield of YGGFL with  $^{18}\text{F}$ FPy-TFP using the Advion NanoTek microfluidic device, which produced a 26% incorporation yield in 12 minutes.<sup>49</sup> However, the microfluidics device could not readily

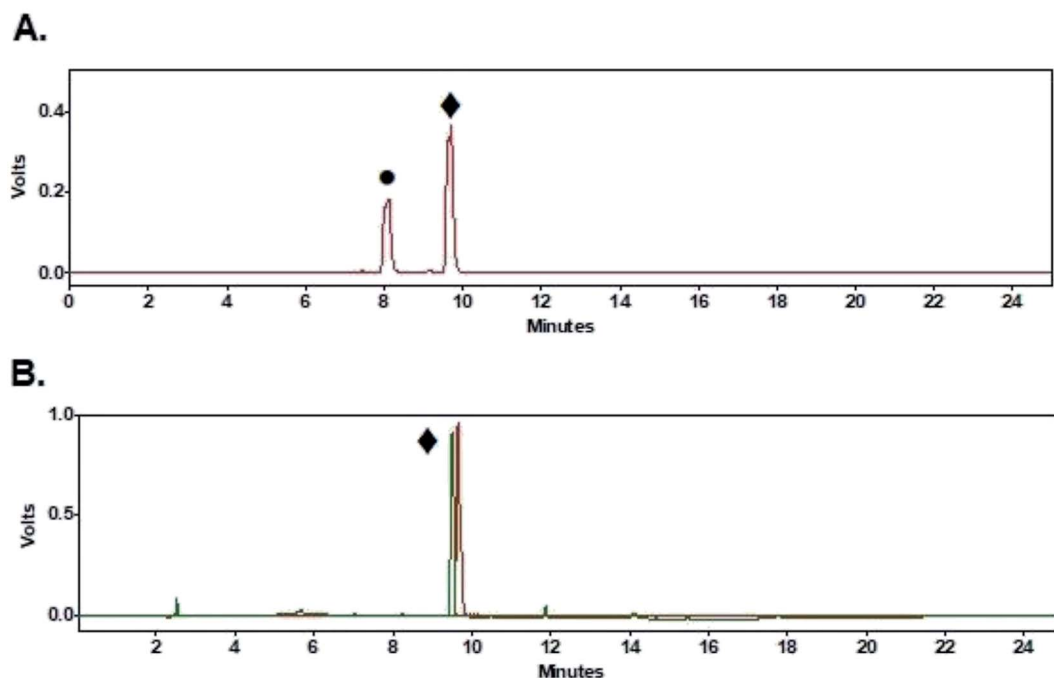

Fig. 6 HPLC chromatogram of radiolabeled  $[^{18}\text{F}]\text{FPy-YGGFL}$  (6) (PMT(gamma)-red, UV(220 nm)-green). (A) Crude radioHPLC chromatogram (peak  $\bullet$  -6- $[^{18}\text{F}]\text{fluoronicotinic acid}$ , peak  $\blacklozenge$  - $[^{18}\text{F}]\text{FPy-YGGFL}$  (6)). (B) Purified HPLC chromatogram co-injected with  $[^{19}\text{F}]\text{FPy-YGGFL}$  (peak  $\bullet$  - $[^{19}\text{F}]\text{FPy-YGGFL}$ , peak  $\blacklozenge$  - $[^{18}\text{F}]\text{FPy-YGGFL}$  (6)).

be used to produce “batch” amounts of  $[^{18}\text{F}]\text{FPy-peptides}$  due to practical limitations to scaling up, such as volume and radiation shielding restrictions. The radiolabeling of cRGDyK using the ELIXYS FLEX/CHEM® radiosynthesizer yielded cRGDyK( $[^{18}\text{F}]\text{FPy}$ ) in  $16.0 \pm 5.6\%$  using  $1.6 \mu\text{mol}$  of peptide. Manual radiolabelings of cRGDfK with  $[^{18}\text{F}]\text{FPy-TFP}$  by Basuli, *et al.* afforded a non-decay corrected yields of 32–43% in a total of 30 minutes, but required 3–5 times the amount of peptide.<sup>46</sup> Other manual approaches for radiolabeling various cRGD-peptides with fluorine-18 have provided yields between 10–35% with total reaction times ranging between 90–218 minutes.<sup>50–55</sup> The yield obtained for cRGDyK( $[^{18}\text{F}]\text{FPy}$ ) was also similar to the previously reported manual solid phase radiolabeling of cRGDyK with 6- $[^{18}\text{F}]\text{fluorobenzoic acid}$  ( $14 \pm 2\%$  yield in 90 minutes).<sup>42</sup> Overall, using the ELIXYS FLEX/CHEM® radiosynthesizer was faster, with a total synthesis time under a 100 minutes including HPLC purification, and provided similar radiochemical yields.

The radiolabeling yields for  $[^{18}\text{F}]\text{FPy-bombesin}$  using the ELIXYS FLEX/CHEM® were  $13.0 \pm 5.2\%$ . Other reports describing the synthesis of radiolabeled bombesin analogues have predominantly used radiometals ( $^{64}\text{Cu}$ ,  $^{68}\text{Ga}$ , and  $^{111}\text{In}$ ) and chelation chemistry, with only a handful describing the manual synthesis of  $^{18}\text{F}$ -bombesin analogues.<sup>56–58</sup> For example, Lys<sup>3</sup>-bombesin, was radiolabeled using 4- $[^{18}\text{F}]\text{fluoroazidobutane}$  in a strain promoted copper free 1,3-dipolar cyclization reaction which proceeded at room temperature in 15 minutes to give a 37% radiochemical yield.<sup>56</sup> Zhang *et al.* reported the radiolabelling of Lys<sup>3</sup>-bombesin using  $[^{18}\text{F}]\text{SFB}$  in sodium borate buffer (pH = 8.5) at 40 °C for 30 minutes, to

produce radiochemical yields of  $31.4 \pm 4.6\%$  with a total synthesis time of  $150 \pm 20$  minutes from fluorine-18.<sup>57</sup> Most recently, a kit-radiolabeling approach of a bombesin derivative with  $[^{18}\text{F}]\text{-NOTA-AlF}$  afforded 50–60% radiochemical yields, but required a high temperature of 95 °C.<sup>58</sup> The previously reported  $^{18}\text{F}$ -radiolabelings of bombesin have produced higher yields than the presented automated  $[^{18}\text{F}]\text{FPy-TFP}$  radiolabeling of bombesin using various radiochemical approaches. The most similar method used was the manual two-step indirect radiolabeling approach utilizing a different activated ester  $[^{18}\text{F}]\text{SFB}$ .<sup>57</sup> This manual  $[^{18}\text{F}]\text{SFB}$  radiolabeling of bombesin<sup>57</sup> employed a different reaction solvent, concentration, and a reaction time of 30 minutes, double that of  $[^{18}\text{F}]\text{FPy-TFP}$ .

Several groups have attempted to develop automated protocols for the production of  $^{18}\text{F}$ -labeled peptides. One of the most complete examples reported to date by Thonon *et al.*, used the FASTLab (GE Healthcare) to produce  $[^{18}\text{F}]\text{SFB}$  *via* both a one- and two-pot method, followed by coupling to an RGD peptide (PRGD2).<sup>36</sup> Higher yields and fewer by-products were observed with the 2-pot approach, which generated  $[^{18}\text{F}]\text{PRGD2}$  in decay-corrected yields of  $13 \pm 3\%$  after 130 minutes with high radiochemical purity (>98%) and high molar activity ( $3873 \pm 1081 \text{ Ci mmol}^{-1}$ ). This semi-automated method included a single manual intervention; the addition of the peptide to the FASTLab module.<sup>36</sup> Tang *et al.* also carried out a semi-automated synthesis wherein  $[^{18}\text{F}]\text{SFB}$  was produced on a TRACERlab FX<sub>FN</sub> synthesizer (GE Healthcare) and then manually coupled to a cell penetrating peptide in a 30 minutes reaction to afford a 10–20% non-decay corrected yields of  $[^{18}\text{F}]\text{SFB-peptide}$ .<sup>48</sup> Valdivia *et al.* generated the  $[^{18}\text{F}]\text{F-pyridyl alkyne}$

prosthetic [ $^{18}\text{F}$ ]FPyKYNE and subsequently coupled it to cRGDyK using a TRACERLab FX<sub>FN</sub> pro module.<sup>59</sup> Following HPLC-purification, the radiolabeled peptide was obtained in 12–18% decay-corrected yields in 125 minutes with high radiochemical purities (>99%) and specific activities (980–2000 Ci mmol<sup>-1</sup>).<sup>59</sup> This report, however, uses copper-mediated prosthetic coupling, which may not be suitable for all applications and due to the reagent's high toxicity additional purification maybe required to ensure copper levels are below the FDA ICH Q3D guidelines. Recently, Inkster *et al.* introduced a thiol-targeted [ $^{18}\text{F}$ ]fluoro-2-cyanobenzothiazole prosthetic, which was subsequently coupled to a cysteine-functionalized cRGDfK peptide using a TRACERLab FX<sub>FN</sub> pro module.<sup>60</sup> Moderate decay-corrected yields of  $7 \pm 1\%$  were reported after 124–132 minutes, along with high radiochemical purities and reasonable specific activities ( $\sim 100$  to 300 Ci mmol<sup>-1</sup>).<sup>60</sup> Overall, ELIXYS FLEX/CHEM® radiosynthesizer radiolabelings produced similar yields within the same timeframe.

## Conclusions

The ELIXYS FLEX/CHEM® radiosynthesizer was specifically designed to support good manufacturing practices (*i.e.* disposable cassettes, software with detailed batch record keeping, *etc.*) for  $^{18}\text{F}$ -radiolabeled compounds, ultimately enabling their rapid translation into the clinic. Until now the fully automated synthesis of  $^{18}\text{F}$ -peptides from fluorine-18 has been challenging in part due to the complexity of synthesis and purification of both the intermediate prosthetic and the final  $^{18}\text{F}$ -peptide. This work represents the fully automated batch production of three [ $^{18}\text{F}$ ]FPy-peptides in a two-step approach from fluorine-18 using the ELIXYS FLEX/CHEM® radiosynthesizer. Minimal amounts of peptide were required to achieve good radiochemical yields 13–26% with high molar activities 1–5 Ci  $\mu\text{mol}^{-1}$  and radiochemical purity >99%. In the future addition of the ELIXYS PURE/FORM®, a HPLC purification module that interfaces with the ELIXYS FLEX/CHEM® radiosynthesizer will enable the whole process to be fully automated.
