Three new metal coordination polymers of bifunctional imidazolate/tetrazolate bridges: the only example of a three-dimensional framework based on rare $[\text{Co}_4(\mu_3-\text{OH})(\mu_2-\text{Cl})_2]^4+$ mixed oxo-chloro-clusters†

Lili Yang, Jian Zhou, Hua-Hong Zou and Qiuling Tang

Three new metal coordination polymers $[\text{Ni}(\mu_2-L)(\text{H}_2\text{O})_2)_n$ (1, HL = 1-tetrazole-4-imidazole-benzene), $[\text{Co}(\mu_2-L)_2)_n$ (2), and $[\text{Co}_2(\mu_3-\text{OH})(\mu_2-\text{Cl})(\mu_2-\text{L})_2(\mu_2-L)_2]_n$ (3) were hydrothermally synthesized and structurally characterized. 1 displays a neutral $[\text{Ni}(\mu_2-L)(\text{H}_2\text{O})_2)_n$ chain built up from the Ni$^{2+}$ ions bridged by deprotonated L$^-$ ligands, while 2 shows another rare neutral $[\text{Co}(\mu_2-L)_2)_n$ chain based on Co$^{2+}$ ions connected by two different coordination modes of the L$^-$ ligand. 3 exhibits a rare $[\text{Co}_2(\mu_3-\text{OH})(\mu_2-\text{Cl})(\mu_2-L)_2]^4+$ mixed oxo-chloro-cluster-based three-dimensional framework with large elliptical channels, which are filled by unprecedented chilopod $[\text{H}_2\text{O})_2]_n$ chains. Both 1 and 2 show antiferromagnetic behavior, while 3 exhibits unusual spin-canting.

Introduction

Magnetic metal coordination polymers with varied fascinating architectures associated with rich magnetic character have attracted considerable attention, due to their potential applications in high-density information storage and processing, quantum computing, and molecular spintronics devices. The appropriate bridging ligands between paramagnetic metal ions have a significant effect on the magnetic behaviors via transmitting magnetic coupling efficiently. Five-membered heterocyclic polyazoles (such as imidazole, triazole and tetrazole) and their derivatives are excellent candidates for active magnetic bridges, because their various bridging modes can aggregate multiple metal ions into polynuclear clusters and generate a new class of bifunctional bridging ligands. The representative bifunctional bridge is 1-tetrazole-4-imidazole-benzene (HL) containing one imidazole and one tetrazole, which was used mainly for the construction of luminescent coordination polymers of d$^{10}$ metal ions (such as Cu$^+$, Ag$^+$, Zn$^{2+}$ and Cd$^{2+}$) owing to its aromatic chromophore and diverse bridging modes. However, its magnetic coordination polymers of paramagnetic metal ions (such as Mn$^{2+}$, Fe$^{2+}$, Co$^{2+}$ and Ni$^{2+}$) have been less explored, and the limited examples are cobalt(n) coordination polymers $[\text{Co}_2(L)_2(\text{HL})(\text{H}_2\text{O})_2][\beta\text{Mo}_6\text{O}_{26}]_0.5^\beta$ and $[\text{Co}_2(L)_2(\text{pbd})]_n(\text{H}_2\text{O})_m$ (H$^2$pd = 1,4-benzene-dicarboxylic acid), all of which show antiferromagnetic behavior, but other important magnetic behaviors have not been documented.

Moreover, the bifunctional bridged ligands containing imidazole and tetrazole groups coordinate to the iron group metal ions to usually generate a variety of metal coordination polymers with octahedrally coordinated metal centers, but their magnetic metal coordination polymers with tetrahedrally coordinated metal centers have not been to date documented, because of synthetic difficulties. The low coordination number of the metal complexes with tetrahedrally coordinated metal centers splitting the d orbitals with a small separation is preferable to form a weak ligand field, which might facilitate the spin-orbital coupling to enhance the magnetic anisotropy, thus resulting in slow magnetic relaxation. It is expected that the...
combination of the magnetic metal ions with tetrahedrally coordinated metal centers and the bifunctional imidazole/tetrazole bridges in the same coordination polymeric frameworks may give a new class of coordination polymers with novel structures and useful magnetic properties. With regard to all aspects stated above, we chose HL as magnetic active bridge, and Co\(^{2+}/Ni\(^{2+} \) ions as the paramagnetic centre based on the listed below considerations: (a) HL containing two types of heterocyclic polyazoles can not only act as a various magnetic capacity that might produce significant magnetic properties, but also serve as a diamagnetic separator, owing to tetrazole and imidazole rings separated by benzene ring. (b) Co\(^{2+} \) and Ni\(^{2+} \) ions are selected as the paramagnetic metal ions that could result in unusual magnetic behaviors.** As a result, three new coordination polymers [Ni\(_{2}\)(H\(_{2}\)O)\(_{2}\)]\(_{n}\) (1), [Co\(_{2}\)-L\(_{2}\)]\(_{2}\) (2), [Co\(_{4}\)(μ\(_{3}\)-OH)\(_{3}\)(μ\(_{2}\)-Cl)\(_{6}\)(μ\(_{4}\)-L)]\(_{n}\)·7H\(_{2}\)O (3) were obtained by hydrothermal methods. 1 shows the Ni\(_{2}\)(μ\(_{3}\)-OH)\(_{2}\)(H\(_{2}\)O)\(_{2}\) chain with six-coordinate Ni\(^{2+} \) center, while 2 exhibits another rare [Co\(_{4}\)-L\(_{2}\)]\(_{n}\) chain based on four-coordinate Co\(^{2+} \) centres. 3 offers the only example of three-dimensional framework incorporating rare mixed oxo-chloro-clusters [Co\(_{4}\)(μ\(_{3}\)-OH)\(_{3}\)(μ\(_{2}\)-Cl)\(_{6}\)]\(_{n}\) mainly because the reported magnetic [M\(_{4}\)Q\(_{8}\)] (Q = OH or halogen element) clusters bonding directly to either tetrazole or its derivatives contain only one type of bridge, such as [Cu\(_{2}\)(μ\(_{3}\)-OH)]\(_{n}\) (M = Mn, Co, Cu)* [M\(_{4}\)(μ\(_{3}\)-OH)\(_{2}\)]\(_{n}\) (M = Mn, Co),** [Co\(_{4}\)(μ\(_{3}\)-Cl)\(_{6}\)]\(_{n}\) and [Co\(_{4}\)(μ\(_{2}\)-Cl)\(_{6}\)]\(_{n}\) but the coexistence of OH and halogen bridges in the same magnetic clusters is only observed in [Co\(_{4}\)(μ\(_{3}\)-OH)\(_{3}\)(μ\(_{2}\)-Cl)\(_{6}\)]\(_{n}\) cluster of 3.

**Experimental**

**General remarks**

All reagents in the preparation procedure were of analytical reagent grade and used without any purification or degassing of solvents. Elemental analyses (C and H) were performed using a PE2400 II elemental analyzer. FT-IR spectra were recorded with a Nicolet Magna-IR 550 spectrometer in dry KBr disks in the 4000–400 cm\(^{-1}\) range. The solid-state UV/Vis spectra were measured at room temperature using a PE Lambda 900 UV/Vis spectrophotometer. Powder X-ray diffraction (XRD) patterns were recorded in the angular range of 2θ = 5–60° on a Bruker D8 advance diffractometer using CuKα radiation. All magnetization of compounds 1–3 were obtained with a Quantum Design MPMS-XL-5 magnetometer.

**Synthesis of [Ni(μ-L)\(_{2}\)(H\(_{2}\)O)\(_{2}\)]\(_{n}\) (1).** The reactants of H\(_{3}\)BO\(_{3}\) (0.1014 g, 1.6 mmol), NiCl\(_{2}\) (0.0899 g, 0.7 mmol), HL (0.0256 g, 0.12 mmol) was stirred for 0.5 h, and then the final mixture was sealed in a 25 mL Teflon lined autoclave. The reaction was heated at 170 °C for 7 days. After cooling to room temperature slowly, purple block crystals of 2 in about 43% (based on HL) were obtained. Anal calc. (found %) for C\(_{20}\)H\(_{18}\)N\(_{12}\)NiO\(_{2}\): C 49.91 (49.96), H 2.93 (2.98), N 32.50 (32.61). IR (KBr, cm\(^{-1}\) ): 3135(s), 1612(m), 1546(m), 1511(s), 1443(m), 1311(m), 747(m), 649(s), 534(m).

**Synthesis of [Co\(_{4}\)(μ\(_{3}\)-OH)\(_{3}\)(μ\(_{2}\)-Cl)\(_{6}\)(μ\(_{4}\)-L)]\(_{n}\)·7H\(_{2}\)O (3).** The reactants of H\(_{3}\)BO\(_{3}\) (0.1093 g, 1.8 mmol), CoCl\(_{2}\) (0.0651 g, 0.5 mmol), HL (0.0266 g, 0.13 mmol) and H\(_{2}\)O (2.0 mL) was stirred for 0.5 h, and then the final mixture was sealed in a 25 mL Teflon lined autoclave. The reaction was heated at 170 °C for 7 days. After cooling to room temperature slowly, red needle-like crystals of 3 in about 63% (based on HL) were obtained. Anal calc. (found %) for C\(_{40}\)H\(_{44}\)Cl\(_{2}\)Co\(_{4}\)N\(_{24}\)O\(_{9}\): C 49.91 (49.96), H 2.93 (2.98), N 34.92 (34.97). IR (KBr, cm\(^{-1}\) ): 3619(m), 3453(m), 3131(s), 1608(s), 1499(vs), 1442(vs), 1363(m), 1284(vs), 1128(w), 1060(s), 825(s), 746(m), 650(m), 561(w), 484(w).

X-ray crystallography

Diffraction intensity data for 1–3 were recorded on a Rigaku Mercury CCD diffractometer using a ω-scan method with graphite monochromated Mo Kα radiation (λ = 0.71073 Å). Absorption corrections were applied using multi-scan technique. The structures of 1–3 were solved by direct methods (SHELXS-97)** and refined by full-matrix least-squares techniques using the SHELXL-97 program.** All non-H atoms were refined anisotropically. The H atoms of L\(^{-1}\) ligands were added geometrically and refined as riding on their parent atoms with fixed isotropic displacement parameters. Relevant crystal collection data parameters and refinement results can be found in Table 1. CCDC numbers are 1892465 (1), 1892466 (2) and 1865774 (3).

**Results and discussion**

**Synthetic aspects**

The crystalline of 1–3 were obtained by the reaction of MCl\(_{2}\) (M = Co, Ni), H\(_{3}\)BO\(_{3}\) and HL in water solution at 170 °C. Although H\(_{3}\)BO\(_{3}\) is not introduced into the final structure, numerous paralleling experiments affirmed that 1–3 cannot be obtained in the absence of H\(_{3}\)BO\(_{3}\), showing that the H\(_{3}\)BO\(_{3}\) may take a role as structural directing agent. The parallel experiments reveal that the reactant stoichiometry and initial reactants can influence the outcome of reaction. For instance, when the quantity of CoCl\(_{2}\) was increased to two times under the similar synthetic procedure to 2, red crystals of 3 containing mixed oxo-chloro-clusters [Co\(_{4}\)(μ\(_{3}\)-OH)\(_{3}\)(μ\(_{2}\)-Cl)\(_{6}\)]\(_{n}\) were isolated. With the aim of preparing an analogue of 3, we tried to replace CoCl\(_{2}\) with NiCl\(_{2}\) alone, but these attempts failed and orange crystal of 1 was the only pure product isolated. The IR spectra of 1 and 3 show the several strong absorptions in the range of 3420–3619 cm\(^{-1}\),
indicative of the characteristic ν_–OH vibration of –OH groups and H_2O molecules, but no similar ν_–OH vibration is observed in 2. The peak at 3131 cm⁻¹ can be assigned to ν_C–H stretching, while the several bands in the range of 1284–1612 cm⁻¹ are attributed to the characteristic ν_C–N, ν_C=O and ν_N=N vibrations of the L⁻ ligand. The phase purities of 1–3 are confirmed by PXRD analysis (Fig. S1†).

**Description of the structure**

**Description of [Ni(μ₂-L)L(H_2O)]_n (1) and [Co(μ₂-L)L]_n (2).** 1 crystallizes in triclinic space group $P1$ and its asymmetric unit contains one unique L⁻ ligand, one coordinated H_2O, and half of a Ni²⁺ ion located at the special position with 2-fold symmetry (Fig. S2a†). The Ni²⁺ ion is octahedrally coordinated to four N atoms from four L⁻ ligands and two H_2O molecules. The Ni–O and Ni–N bond lengths are normal and call for no further comment. The neighboring complex [Ni(H_2O)]⁶⁺ cations are bridged by double L⁻ ligands to give a chain [Ni(μ₂-L)L(H_2O)]_n (Fig. 1a) with a Ni–Ni distance of 10.98 Å.

2 crystallizes in monoclinic space group $C2/c$. The asymmetric unit contains one unique Co²⁺ ions and two L⁻ ligands (Fig. S2b†). Each Co²⁺ ion adopts a tetrahedral coordination mode comprised of four N atoms from four L⁻ ligands. The Co–N bond lengths are in the range of 1.995(3)--2.018(3) Å, comparable to corresponding values (1.855(5)--2.155(4) Å) in other compounds. The L⁻ ligand shows two different bridging modes, namely, μ₂–N1xN3 and μ₂–N7xN12. The neighboring Co²⁺ ions are bridged by μ₂–N1xN3 bridging ligand to form a [Co₂L₂] dimer with a Co...Co distance of 10.54 Å. The [Co₂L₂] dimer units are interconnected via μ₂–N7xN12 bridging ligand to form a chain [Co(μ₂-L)L]_n with elliptical ring (Fig. 1b).

**Description of [Co(μ₂-OH)L₂(μ₂–Cl)₂(μ₂–L)L]₅ (3).** 3 crystallizes in monoclinic space group $C2/c$ and its asymmetric unit contains two Co²⁺ ions, two L⁻ ligands, one Cl⁻ anion, one –OH group, three and half of H_2O, where O3W atom is seated at the special position with 2-fold symmetry (Fig. 2a).

![Fig. 1](image1.png)

**Fig. 1** The structures of [Ni(μ₂-L)L(H_2O)]_n (a) and [Co(μ₂-L)L]_n (b) chains. All H atoms bonded to C and O atoms have been omitted for clarity.

![Fig. 2](image2.png)

**Fig. 2** (a) The asymmetric unit of 3 with labeling scheme. (b) [Co₄(μ₂–OH)L₂(μ₂–Cl)L]₄⁺ mixed oxo-chloro-cluster [symmetry operation: (i) $x$, $-y$, $1-z$]. (c) The layer built from [Co₄(μ₂–OH)L₂(μ₂–Cl)L]₄⁺ clusters and L1 ligands. (d) Three-dimensional framework of 3. (e) Chilopod ([H_2O]_1)₅ chain. H atoms bonded to C atoms are omitted for clarity.

![Fig. 3](image3.png)

other compounds. There are two bridging modes of L–ligand [denoted as L1 and L2, Fig. S3†] in 3. The L1 ligand shows a μ2-xN1-xN2-xN3-N4-xN6 bridging mode, while the L2 ligand exhibits a μ2-xN8-xN11 bridging mode. All atoms in L1 and L2 are not coplanar, mainly because the dihedral angle of benzene ring and imidazole ring is 8.19° for L1 and 26.34° for L2, and the dihedral angle of benzene ring and tetrazole ring is 65.31° for L1 and 8.29° for L2. Four Co2+ ions are bridged by two μ3-OH groups and two μ3-Cl– ions to form a novel tetra-nuclear [Co4(μ3-OH)2(μ3-Cl)3]4+ mixed oxo-chloro-cluster with Co···Co distances of 3.127–3.596 Å (Fig. 2b). This cluster might be also viewed as a derivative of the butterfly-shaped [Co4(μ3-OH)2] cluster, whose Co2+ ions are further bridged by two μ3-Cl– ions.

The [Co4(μ3-OH)2(μ3-Cl)3]4+ clusters are interconnected by L1 ligands to form an infinite [Co4(μ3-OH)2(μ3-Cl)3]4+ cluster-based 2-D layer (Fig. 2c). The nearest Co···Co distance between adjacent clusters spanned by tetrazole ring of L– ligand is much shorter than that by whole L– connector (4.21 versus 10.43 Å), resulting in the significant superexchange interactions within the Co-tetrazole ribbon. These layers are further bridged by L2 ligands to generate a three-dimensional network structure with large elliptical channels filled by [(H2O)7]n chilopod chains (Fig. 2d). The free H2O molecules are interconnected via O–H···O H-bonds to form chilopod [(H2O)7]n chain (Fig. 2e), which contains cyclic hexamer (H2O)6 with a pseudo-crown configuration (Fig. S4†) and H2O(2W) foot. The average O···O distance of 2.894 Å is close to the corresponding value (2.85 Å) in liquid H2O.4,9 So far, some infinite cyclic water chains have been reported, as exemplified by T4(1), T4(1)6(1), T4(2)6(2), T5(2), T6(1) and T6(2) modes,17 but their cyclic chains decorated by branch-like H2O molecules are very rare.18 The [(H2O)7]n chain in 3 can be regarded as T6(1) chain decorated by one branch-like H2O molecule, which exhibits a new type of cyclic water chain. Notably, some metal coordination polymers of L–ligands have been reported, but no water chains are observed within their extended architectures.5,6 Therefore, 3 offers the only example of three-dimensional architecture based on L–ligands with channels filled by chilopod [(H2O)7]n chains.

More interestingly, some three-dimensional extended frameworks are built up from the linkages of metal ions and a mixed bridge of L– ligand and aromatic carboxylate to date,18 but similar three-dimensional architectures containing only

one type of $L^-$ ligand are relatively scarce, and the limited examples include $[\text{Cu}_2(\mu_1-L)_2]_\infty$ with 4-connected SrAl topology constructed by simple Cu$^+$ ions and $\mu_1-L$ bridges, and $[\text{Cu}_2Cl(\mu_2-L)]_\infty$ with bimodal fsc-3,5-5mcne-1 topology based on the combination of $L^-$ ligands and dimeric $[\text{Cu}_2Cl]^{2+}$ cluster units, in which the number of metal ions within the cluster unit is not more than two, but the number of $\text{Co}^{2+}$ ions in the $[\text{Co}_4(\mu_3-OH)_2(\mu_2-Cl)]^{4+}$ cluster of 3 is four. Hence, 3 is the only example of 3-D framework based on the linkages of high-nuclear magnetic $[\text{Co}_4(\mu_3-OH)_2(\mu_2-Cl)]^{4+}$ clusters and $L^-$ ligands.

**Magnetic properties**

The magnetic susceptibilities of polycrystalline samples of 1–3 were measured on cooling from 300 to 2 K in an applied field of 1000 Oe. The values of $\chi_M/T$ at 300 K are 1.25 cm$^3$ K mol$^{-1}$ for 1 and 2.59 cm$^3$ K mol$^{-1}$ for 2 (Fig. 3), which are higher than the spin-only value for one isolated Ni$^{3+}$ ion (1.0 cm$^3$ K mol$^{-1}$, $S = 1$) and Co$^{2+}$ ion (1.875 cm$^3$ K mol$^{-1}$, $S = 3/2$). This phenomenon in 2 is very common for Co$^{2+}$ due to the significant orbital contribution, and it in 1 could result from the orbital contribution of the $^3A_2g$ ground state of the high-spin octahedrally coordinated Ni$^{3+}$ ion. The values of $\chi_M/T$ slowly decrease upon decreasing temperature and the $\chi_M/T$ values are 1.21 cm$^3$ K mol$^{-1}$ for 1 (at 20 K) and 2.23 cm$^3$ K mol$^{-1}$ for 2 (at 70 K). On further cooling, another sharply decreases of $\chi_M/T$ are observed, to 0.52 cm$^3$ K mol$^{-1}$ for 1 and 1.31 cm$^3$ K mol$^{-1}$ for 2 at 2 K. The plots of $\chi_M/T$ versus magnetic field up to 5 T following cooling and the isothermal magnetization at 2 K and remnant magnetization at 2 K.

**Conclusions**

Although a few low-dimensional magnetic metal coordination polymers of bifunctional bridges containing imidazolate and tetrazolate groups have been reported to date, they generally exhibit antiferromagnetic behavior. 3 not only presents the only example of three-dimensional framework based on the linkages of rare $[\text{Co}_4(\mu_3-OH)_2(\mu_2-Cl)]^{4+}$ mixed oxo-chloro-clusters and bifunctional imidazolate/tetrazolate bridges, but also show unusual spin-canting. Furthermore, the similar bifunctional imidazolate/tetrazolate bridges coordinate to the magnetic metal ions to form varied metal coordination polymers with octahedrally coordinated metal centers, but 3 is the only example of the magnetic tetrahedral metal coordination polymer with tetrahedrally coordinated metal centers of bifunctional imidazolate/tetrazolate bridges. These results enrich structural types of magnetic metal coordination polymers of bifunctional imidazolate/tetrazolate bridges, and offer possibilities to prepare other novel metal coordination polymers with important magnetic behavior using paramagnetic metal ions in combination with other bifunctional imidazolate/tetrazolate bridges.
