Strain sensitivity of band structure and electron mobility in perovskite BaSnO₃: first-principles calculation

Yaqin Wang,^{id}*^{ab} Runqing Sui,^a Mei Bi,^a Wu Tang^b and Sude Ma^a

A first-principles electronic structure calculation is utilized to contrastively investigate the crystal structure, band structure, electron effective mass and mobility of perovskite BaSnO₃ under hydrostatic and biaxial strain. Strain-induced changes in relative properties are remarkable and more sensitive to hydrostatic strain than biaxial strain. The structure of BaSnO₃ remains cubic under hydrostatic strain, while it becomes tetragonal under biaxial strain. Originating from the strain sensitivity of the Sn 5s orbitals in the conduction band minimum, the band gaps of BaSnO₃ decrease for both types of strain from -3% to 3%. BaSnO₃ under tensile hydrostatic strain exhibits higher electron mobility than it does under tensile biaxial strain because of the smaller electron effective mass in the corresponding strain. In contrast, the opposite phenomenon exists in compressive strain. Our results demonstrate that strain could be an alternative way to modify the band gap and electron mobility of BaSnO₃.

1 Introduction

Recently perovskite-type oxide BaSnO₃ has become a research hotspot, due to its high electron mobility and visible light transmittance at room temperature, as well as thermal stability.¹ The cubic BaSnO₃ with a band gap of 3.1 eV is stable at temperatures up to 1000 °C.² Its high visible optical transparency makes it is commonly used as a transparent electrode material or as electronic components for power devices, and it is regarded as a good substitute material for the traditional transparent conductive oxides. On the other hand, due to the Sn 5s orbitals on the bottom of the conduction band, BaSnO₃ has a high electron mobility at room temperature, with values of 320 cm² V⁻¹ s⁻¹ (ref. 3) and 150 cm² V⁻¹ s⁻¹ (ref. 4) for single crystal and film structures, respectively. These properties suggest that BaSnO₃ is an ideal channel material in perovskite heterostructures, compared with the traditional SrTiO₃ thin films. In the past 50 years, the best electron mobility and conductivity of SrTiO₃ thin film has been 10 cm² V⁻¹ s⁻¹ and 500 S cm⁻¹ at room temperature,¹ resulting in the related interesting properties of the LaAlO₃/SrTiO₃ heterostructure being limited to low temperatures.⁵ The appearance of BaSnO₃ is expected to make the quantum effect appear in the perovskite heterostructure at room temperature, expanding the application ranges of perovskite electronic devices.

To date, previous studies have used many methods to modify the band gap and electron mobility of BaSnO₃ thin films. The typical method is “Doping engineering” with La into the Ba site and Sb into the Sn site. The band gap can be effectively adjusted from 3.48 eV to 4.23 eV.^{2,6–8} However, the electron mobility can only reach 70–150 cm² V⁻¹ s⁻¹ at room temperature. In the earliest work, the electron mobility of (Ba, La)SnO₃ thin films on SrTiO₃ (001) substrate obtained by Kim *et al.*³ was 70 cm² V⁻¹ s⁻¹ at a doping level of 4 × 10²⁰ cm⁻³. Kookrin Char *et al.*⁹ and Shiogai *et al.*¹⁰ improved the electron mobility of La–BaSnO₃ thin films to 80 cm² V⁻¹ s⁻¹ and 78 cm² V⁻¹ s⁻¹ by depositing the BaSnO₃ and (Ba, Sr)SnO₃ buffer layers on SrTiO₃ (001) substrate, respectively. K. H. Kim *et al.*¹¹ has reported that using single crystal BaSnO₃ (001) as substrate can reduce the appearance of dislocation in BaSnO₃ thin films, increasing the electron mobility up to 102 cm² V⁻¹ s⁻¹. Bharat Jalan *et al.*,¹ Lebens Higgins *et al.*,¹² and Susanne Stemmer *et al.*⁴ have deposited La–BaSnO₃ thin films with ultra-high crystallinity by molecular beam epitaxy, improving the electron mobility to 120 cm² V⁻¹ s⁻¹, 81 cm² V⁻¹ s⁻¹, and 150 cm² V⁻¹ s⁻¹, respectively. All these studies indicate that due to the ionized impurities scattering caused by the La(Sb) atom doping in the La(Sb)–BaSnO₃ thin films, the electron mobilities of La(Sb)–BaSnO₃ are limited. So far, the highest electron mobility of BaSnO₃ film obtained at room temperature is 150 cm² V⁻¹ s⁻¹. Thus, other methods to tune the band gap and electron mobility of BaSnO₃ are needed.

The method of “Strain engineering” is a widely used method to obtain desired properties of materials. Many studies have indicated that external stresses such as hydrostatic pressure and internal strains from lattice and thermal mismatch can

alter the structure and electronic properties of semiconductors. The band type of ultrathin [0001] ZnO nanowire changes from direct to indirect under uniaxial compressive strain, along with the structural transition from wurtzite to hexagonal.¹³ The band gaps of Sn oxides with SnO₆ octahedra decrease (increase) by 0.8–1.0 eV with a hydrostatic strain of 2% (−2%), showing that they are highly sensitive to hydrostatic strain.¹⁴ The tensile biaxial strain from the substrate destroys the two-dimensional electron gas (2DEG) at the LaAlO₃/SrTiO₃ (001) interface, while the compressive biaxial strain induces the 2DEG and increases the critical thickness of LaAlO₃ thin films for the insulator-to-metal transition.^{15,16} Also, the tensile biaxial strain is experimentally demonstrated to be effective at reducing the mobility of the 2DEG at the LaAlO₃/SrTiO₃ (001) interface.¹⁶ The epitaxial strain dependence of the spontaneous polarizations and Curie temperatures varies considerably for different ferroelectric thin film systems, such as BaTiO₃, PbTiO₃, LiNbO₃, and BiFeO₃.^{17–20}

To tune the electronic properties of BaSnO₃ through epitaxial in-plane misfit strains and external hydrostatic pressure, we have used first-principles calculations to demonstrate a detailed study of strain engineering of BaSnO₃. The changes in crystal structure, electronic structure, electron effective mass and mobility due to the imposed strain have been investigated. Some commercially available substrate materials have also been concluded in our work.

2 Methods and models

In this work, all the density functional theory (DFT) simulations were performed using the Vienna Ab initio Simulation Package (VASP).²¹ The electron-ion interactions were described by the projector augmented-wave (PAW)²² pseudopotentials method. A cutoff energy of 440 eV for the plane-wave basis set, and a Monkhorst–Pack *k*-point mesh of 6 × 6 × 6 for the unit cell of BaSnO₃ was employed to get well-converged results. The force tolerance on every atom was smaller than 0.01 eV Å^{−1}. For the electronic exchange–correlation interactions, the Heyd–Scuseria–Ernzerhof (HSE06)²³ hybrid functional theory was used, and 43% contribution of Hartree–Fock (HF) exchange in HSE06 functional theory was set to obtain the accurate band gap of BaSnO₃.

A cubic perovskite BaSnO₃ unit cell was used to model the variations of properties under hydrostatic strain ($\epsilon_{xx} = \epsilon_{yy} = \epsilon_{zz}$) and biaxial strain ($\epsilon_{xx} = \epsilon_{yy} \neq \epsilon_{zz}$) from −3% to 3%, at intervals of 1%. The relaxed lattice constant of 4.129 Å from HSE06 theory was used to calculate the properties of unstrained BaSnO₃. The lattice parameters along the *x*, *y*, and *z*-axes were adjusted to simulate various applied hydrostatic strains from −3% to 3%, and allowing the atoms to fully relax. For the case of biaxial strain, the lattice parameters along the *x* and *y*-axes were changed equally, and the structure was allowed to relax in the *z*-axial direction. The electron effective mass was determined by analyzing the calculated band structures at the energy band extremum using the standard equation²⁴

$$\frac{1}{m_i} = \frac{1}{\hbar^2} \frac{\partial^2}{\partial k^2} E_{\text{cond}}(k_{\text{CBM}}) \quad (1)$$

where i (\parallel , \perp) represents the direction of the calculated electron effective mass in Fig. 1.

3 Discussion and results

Strain-free BaSnO₃ has a cubic perovskite structure and belongs to the *Pm3m* space group. It is composed of a corner-sharing SnO₆ octahedron, with a Ba²⁺ filling in the structure. For the case of hydrostatic strain ($\epsilon_{xx} = \epsilon_{yy} = \epsilon_{zz}$), BaSnO₃ remains cubic [Fig. 1(a)] and is the same as strain-free BaSnO₃. However, when biaxial strain ($\epsilon_{xx} = \epsilon_{yy} \neq \epsilon_{zz}$) is imposed, the symmetry is changed and the crystal structure becomes tetragonal [Fig. 1(f)]. Along with the different structure changes between biaxial and hydrostatic strain, BaSnO₃ also presents discrepant electronic properties. Fig. 1(c), (d) and (e) show typical band structures of BaSnO₃ under −3% hydrostatic strain, 0 strain and −3% biaxial strain, respectively. The results show that BaSnO₃ displays indirect band gaps in both strain and strain-free structures. The conduction band minimum (CBM) under biaxial and hydrostatic strain both occurs at the *T* point. However, originating from the different structural symmetry of BaSnO₃ under biaxial and hydrostatic strain, the valence band maximum (VBM) appears at the *R* point under biaxial strain and at the *A* point under hydrostatic strain. The electron effective mass is determined by analyzing the calculated band structure near *T* along the *z*-axial direction in reciprocal space (m_{\parallel}) and along the *x*-axial or *y*-axial directions (m_{\perp} , perpendicular to the *z*-axial direction), as indicated in Fig. 1(b) and (g). According to the symmetry, it can be obtained that the electron effective masses in the *x*, *y*, and *z*-axials are equal under hydrostatic strain ($m_{\parallel} = m_{\perp}$), while they are shown to be different under biaxial strain ($m_{\parallel} \neq m_{\perp}$). The accurate values are presented in the following content.

In order to clearly present structural changes of BaSnO₃ under different strains, the lattice constants, bond lengths and volumes of BaSnO₃ under different biaxial and hydrostatic strain are shown in Fig. 2. The lattice parameter of strain-free cubic BaSnO₃ is 4.129 Å from HSE calculation, in agreement with the experimental value of 4.115 Å.²⁵ The in-plane lattice constant *a* and bond length d_a ($=a/2$) increase with increasing biaxial strain from compressive strain to tensile strain. The out-of-plane lattice constant *c* and bond length d_c ($=c/2$) decrease with the biaxial strain, resulting from the Poisson effect. For the case of hydrostatic strain, BaSnO₃ remains cubic, and the change of lattice constants ($a = c$) and bond lengths ($d_a = d_c$) is the same as the shift of *a* and d_a under biaxial strain, that is, an increase with hydrostatic strain from compressive strain to tensile strain. As a result, the volumes of BaSnO₃ under hydrostatic strain shift significantly toward higher values than that under biaxial strain. The volume of BaSnO₃ is 80.13 Å³ under 3% hydrostatic strain, which is about 4 Å³ larger than that of BaSnO₃ with the same biaxial strain.

Next, we carried out comparison studies for the electronic properties of BaSnO₃ under different strain. Table 1 lists the lattice and electronic parameters of strain-free BaSnO₃. The band gap is obviously underestimated to be around 0.325 eV from the GGA calculation. The value from HSE calculation is

Fig. 1 (a and f) are the BaSnO₃ unit cell under -3% hydrostatic strain (cubic structure) and -3% biaxial strain (tetragonal structure). The green, gray and red circles represent Ba, Sn and O atoms, respectively. a and c are the lattice constants of the BaSnO₃ unit cell. d_a and d_c are the distances between Sn and O atoms in horizontal and vertical planes, respectively. (c, d and e) are the calculated band structures of BaSnO₃ under -3% hydrostatic strain, 0 strain and -3% biaxial strain, respectively. (b and g) are the Brillouin zones of the cubic structure and tetragonal structure indicating high-symmetry directions. Red arrows show the direction along which the electron effective masses are calculated.

3.091 eV, consistent with the experimental values of 3.1 eV.²⁸

Fig. 3 shows the relationships between the calculated band gap from HSE calculation and biaxial strain or hydrostatic strain. The band gap of BaSnO₃ decreases with increasing strain from compressive strain to tensile strain for both biaxial and hydrostatic strain. With an increase in biaxial and hydrostatic strain from -3% to 3%, the values drop from 3.70 eV to 2.51 eV, and 4.46 eV to 1.89 eV, respectively. The linear relationships under biaxial strain and hydrostatic strain, respectively, can be expressed as follows:

$$E_{g,bi} = 3.096 - 19.69\varepsilon_{xx} \quad (2)$$

$$E_{g,hyd} = 3.129 - 42.72\varepsilon_{xx} \quad (3)$$

To evaluate the change of band gap with strain, we further calculated the deformation potentials, which can determine the quality of device modeling³³ and are difficult to obtain from experiment.³⁴ The sum deformation potential under in-plane strain can be calculated by the following equation:³³

$$\Delta E_g^X = D_{\perp}^X(\varepsilon_{xx} + \varepsilon_{yy}) \quad (4)$$

where X represents $\Gamma - R$ and $\Gamma - \Gamma$ for BaSnO₃ under biaxial strain, and $\Gamma - A$ and $\Gamma - \Gamma$ for hydrostatic strain. Table 2 lists the calculated deformation potentials, which are important for BaSnO₃ to predict the band positions under realistic strain.

To further explain the change of band gap versus strain, we plotted the energy of the CBM and VBM as a function of strain in Fig. 3. The variation tendency of the CBM is more remarkable than that of the VBM under both biaxial and hydrostatic strain. The CBM of BaSnO₃ is mainly comprised of Sn 5s orbitals, while the VBM consists of O 2p orbitals. The results thus indicate that the Sn 5s orbitals play a major role in the strain sensitivity of the band gap in BaSnO₃.

In addition to the band structure, we also calculated the electron effective mass for the conduction band minimum at the Γ point along the x , y and z -axial directions in reciprocal space. The calculated longitudinal and transverse effective masses at the Γ point in strained BaSnO₃ are shown in Fig. 4. The electron effective mass of BaSnO₃ changes remarkably with the strain from -3% to 3%. For the case of biaxial strain, the transverse and longitudinal electron effective masses both

Table 1 The lattice parameters a , indirect band gap E_g^{ind} , and electron effective mass m_e^* for strain-free BaSnO₃ calculated by GGA and HSE06 methods, compared to the available data

	GGA	HSE06	Exp.	GGA-Ref.	HSE06-Ref.
a (Å)	4.186	4.129	4.115 (ref. 25)	4.142 (ref. 26)	4.13 (ref. 27)
E_g^{ind} (eV)	0.325	3.091	3.1 (ref. 28)	0.74 (ref. 26)	3.22 (ref. 29)
m_e^*/m_0	0.196	0.212	0.20–0.43 (ref. 30)	0.03–0.08 (ref. 26)	0.22, ²⁹ 0.2, ³¹ 0.21 (ref. 32)

decrease monotonically with increasing biaxial strain. The difference between transverse and longitudinal electron effective mass is very small under tensile strain and can be ignored under compressive strain. Since BaSnO₃ is always cubic under hydrostatic strain, the transverse and longitudinal electron effective masses are equal and decrease linearly from compressive hydrostatic strain to tensile hydrostatic strain. The variations of effective mass with volume for BaSnO₃, defined as $d\ln m/dV$, is -2.39 for both m_{\parallel} and m_{\perp} , which is larger than that for GaN and AlN reported by Dreyer *et al.*³⁵

To estimate the electron mobility of BaSnO₃, we calculated the average electron effective mass for conductivity using the following equation:³⁶

$$\frac{1}{m_e^*} = \frac{1}{3} \left(\frac{1}{m_{\parallel}} + \frac{2}{m_{\perp}} \right) \quad (5)$$

where m_{\parallel} and m_{\perp} are the longitudinal electron effective mass along the z -axial direction and transverse electron effective

mass along the x -axial or y -axial directions, respectively. m_0 represents the effective mass for a free electron. The average electron effective mass of strain-free BaSnO₃ using HSE functional theory is $0.212m_0$, which is comparable with the experimental values of 0.20 – $0.43m_0$,³⁰ and the calculated values from other researchers of $0.22m_0$,²⁹ $0.2m_0$,³¹ and $0.21m_0$.³² The average electron effective mass decreases linearly under both biaxial and hydrostatic strain. With the increase in strain from -3% to 3% , the electron effective mass decreases from $0.25m_0$ to $0.18m_0$ under hydrostatic strain, while it shifts from $0.23m_0$ to $0.20m_0$ under biaxial strain. Thus it is more sensitive to hydrostatic strain than biaxial strain.

The change of electron effective mass with strain can be utilized to estimate the influence of strain on the electron mobility by the equation:³⁷ $\mu = e\langle\tau\rangle/m_e^*$, with the assumption that $\langle\tau\rangle$ is a constant. e , m_e^* , and $\langle\tau\rangle$ are the charge, electron effective mass, and average scattering time, respectively. The normalized electron mobility (μ/μ_0) for BaSnO₃ under different biaxial and hydrostatic strain with respect to the strain-free BaSnO₃ are presented in Fig. 5. μ_0 refers to the electron mobility of strain-free BaSnO₃. Our results show that the electron mobility is more sensitive to hydrostatic strain than biaxial strain. With the strain change from -3% to 3% , the normalized electron mobility monotonously increases from 0.86 to 1.16 under biaxial strain, while increasing from 0.74 to 1.39 under hydrostatic strain. Both tensile hydrostatic and biaxial strain can enhance the electron mobility, while the compressive strain reduces the electron mobility.

Table 2 The deformation potentials of perovskite BaSnO₃ under small in-plane biaxial and hydrostatic strain, as defined in eqn (4)

	X	D_{\perp}^X (eV)
Biaxial strain	$\Gamma - R$	-9.99
Biaxial strain	$\Gamma - \Gamma$	-9.81
Hydrostatic strain	$\Gamma - A$	-21.36
Hydrostatic strain	$\Gamma - \Gamma$	-21.45

Fig. 4 The dependence of electron effective mass for BaSnO₃ under different biaxial and hydrostatic strain. The average electron effective mass for conductivity (m_e^*), longitudinal electron effective mass (m_{\parallel}) and transverse electron effective mass (m_{\perp}) shown in Fig. 1 are presented. m_0 is the effective mass for a free electron.

Fig. 5 The normalized electron mobility (μ/μ_0) for BaSnO_3 under different biaxial and hydrostatic strain with respect to the strain-free BaSnO_3 .

The variations of band gap and electron mobility compared with the strain-free BaSnO_3 as a function of biaxial strain are shown in Fig. 6. The results show that the biaxial strain has opposite effects on the band gap and electron mobility. Compressive strain enhances the band gap and decreases the electron mobility, while tensile strain decreases the band gap and improves the electron mobility. For a change in compressive strain from 0 to 3%, the band gap increases by 19.6%, and the electron mobility drops 13.9%. On the other hand, for tensile strain, $\Delta E_g/E_g$ is negative, and drops linearly with the strain from 0 to 3%. The tensile strain results in a significant improvement of electron mobility, for example, $\Delta\mu/\mu_0$ is equal to 15.6% under 3% tensile strain.

Further, we expect that the biaxial strains in ultrathin epitaxial BaSnO_3 films on suitable substrates can modify the electron mobility and band gap. A number of materials are investigated and some commercially available substrate materials are marked on Fig. 6. It should be pointed out that the

Fig. 6 The variations of band gap and electron mobility of strained BaSnO_3 in comparison to the strain-free BaSnO_3 as a function of biaxial strain. Some commercially available substrate materials are marked on the figure.

substrates marked on the figure only rely on the lattice parameters. However, the strain is not only from the lattice mismatch, but also from the thermal expansion parameters between the film and substrate. In fact, it also depends on the preparation conditions, film thickness, misfit dislocations at the film-substrate interface, and external conditions. The lattice constants of SrZrO_3 and LaInO_3 are similar to that of BaSnO_3 , which seems suitable for epitaxial growth to avoid possible misfit dislocations at the film-substrate interface.

4 Conclusions

In summary, we have studied the structure, electronic properties, electron effective mass and mobility of perovskite BaSnO_3 over a wide range of hydrostatic and biaxial strain using first-principles density functional theory calculations. Compared to the biaxial strain, the properties of perovskite BaSnO_3 are more sensitive to hydrostatic strain. The structure of BaSnO_3 remains cubic for the case of hydrostatic strain, while it changes to tetragonal under biaxial strain. With the change in biaxial and hydrostatic strain from -3% to 3% , the band gaps linearly drop from 3.70 eV to 2.51 eV, and 4.46 eV to 1.89 eV, respectively. The Sn 5s orbitals of the conduction band minimum play a major role in this strain sensitivity of the band gap. Due to the change of electron effective mass of BaSnO_3 under strain, BaSnO_3 under tensile strain exhibits higher normalized electron mobility than strain-free BaSnO_3 , with a value of 1.16 under biaxial strain and 1.39 under hydrostatic strain. On the other hand the compressive strain reduces the normalized electron mobility of BaSnO_3 to 0.86 and 0.74 under biaxial and hydrostatic strain, respectively. Hence, the results are a guidance to experimental study, and are also useful to design electronic devices using strained perovskite BaSnO_3 .
